EXECUTIVE SUMMARY

The Bayou Pierre River Basin is one of the most diverse basins in Louisiana. Rapid development is taking place in the extreme northern area of the basin. The diverse basin has a complex set of resource concerns. A Technical Steering Committee (TSC) representing private and public entities was charged with identifying existing conditions, resource problems, and developing an assortment of alternative solutions, within the study area. The local sponsors for the study are: Caddo, De Soto, Natchitoches, Red River, and Sabine Soil and Water Conservation Districts; Caddo Levee District; Caddo Parish Commission; City of Shreveport; De Soto Parish Police Jury; Natchitoches Levee and Drainage District; Police Jury of Natchitoches Parish; Police Jury of Sabine Parish; Red River Parish Police Jury, and the Red River Levee and Drainage District.

The objectives of the study are to identify and analyze the related land and water resources within the area and develop a strategy to enhance the quality of life of the residents of Caddo, De Soto, Natchitoches, Red River, and Sabine Parishes. This study helped to bring all concerns forward and to get groups together to identify and address resource concerns of the study area.

Five Public Scoping Meetings were held throughout the basin. From the five public meetings, 103 Problems/Issues/Concerns were recorded. Due to the similarity of the problems/issues/concerns from the citizens, they were grouped into broad-based categories. Sixty percent of the comments were related to flooding, 14% were related to planning, 8% were concerned with water quality issues, 7% were recreation comments and 4 % dealt with watershed protection.

Alternative solutions were developed to address the dominant problems identified above. While no funding mechanism is in place to implement recommended solutions, potential sources have been identified. Programs available through the United States Department of Agriculture and Department of Interior offer financial assistance to landowners to implement wetland and floodplain restoration measures. Financial assistance through the Statewide Flood Control program may be available to implement some of the structural flood protection alternatives.

INTRODUCTION

BACKGROUND

In June 1995, The Natural Resources Conservation Service (NRCS) received a letter from the Red River Levee and Drainage District requesting that NRCS (the Soil Conservation Service at that time) initiate a River Basin Study of Bayou Pierre. The initial request from the drainage district expressed concern with flooding and drainage problems in the basin. Since the first request in 1995, NRCS has received thirteen additional letters of sponsorship resulting in a total of fourteen sponsors for this cooperative study. The study began in 1999.

AUTHORITY

The Bayou Pierre Cooperative River Basin Study (BPCRBS) is authorized under Section 6 of Public Law 83-566 (PL 83-566), the Watershed Protection and Flood Prevention Act, as amended. This law was legislated under the tenure of the 83rd Congress in August 1954. It authorizes the United States Department of Agriculture (USDA) to cooperate with other federal, state, and local agencies to make surveys and investigations of the watersheds of rivers and other waterways as a basis for the development of coordinated programs. Such surveys form the framework for appraising water and related land resources and formulating alternatives for conservation, use, and development.

SPONSORS, PARTICIPANTS, AND COOPERATING ENTITIES

The local sponsors for the study are: the Red River Levee and Drainage District Coushatta, Louisiana; Natchitoches Soil and Water Conservation District, Red River Soil and Water Conservation District, De Soto Soil and Water Conservation District, Sabine Soil and Water Conservation District, Caddo Soil and Water Conservation District, Natchitoches Levee and Drainage District, Police Jury of Natchitoches Parish, Red River Parish Police Jury, Police Jury of Sabine Parish, Caddo Parish Commission, De Soto Parish Police Jury, Caddo Levee District, and the City of Shreveport.

Other participants in the study are United States Geological Survey (USGS), United States Army Corps of Engineers (USACE), United States Fish and Wildlife Service (FWS), Federal Emergency Management Agency (FEMA), Environmental Protection Agency (EPA), U. S. and State Senators and Representatives, Louisiana Department of Environmental quality (LDEQ), Louisiana Department of Transportation and Development (LDOTD), Louisiana Cooperative Extension Service (LCES), Louisiana Department of Agriculture and Forestry (LDAF), Louisiana Department of Wildlife & Fisheries (LDWF), Louisiana Audubon Council, Coalition of Wallace Lake Flood Victims, Red River Coalition, Red River Valley Association (RRVA), Red River

Waterway Commission (RRWC), land owners and other stakeholders within the basin area.

The planning process for the study was a locally led initiative consisting of a Technical Steering Committee (TSC). The Technical Steering Committee is chaired by Cliff Conine of the Natchitoches Levee and Drainage District. Members of the TSC served on this interdisciplinary team to coordinate a broad-based planning effort to analyze and address the problems within the study area. The TSC was composed of members of the above listed sponsors and cooperating agencies.

OBJECTIVES OF THE REPORT

The objectives of the study are to identify and analyze the related land and water resources within the area and develop a strategy to enhance the quality of life of the residents of Caddo, De Soto, Natchitoches, Red River, and Sabine Parishes. The study will:

1. Establish baseline conditions and identify problems of the land and water resources within the study area;
2. Develop alternatives that address the problems in a manner that is environmentally, economically, and socially sound and acceptable to the residents of the study area;
3. Outline a broad-based plan to address the problems of the area and identify Federal, state, and local agencies and organizations that provide technical and financial assistance.

USE OF THE REPORT

The report will serve as a guide to the best use or combination of uses of water and related land resources to meet foreseeable short-term and long-term needs in the basin. Ultimately the report will be used in part or entirety by individuals, agencies, and other stakeholders in solving problems and funding measures to improve the quality of life within the study area.

MAPS AND FIGURES

The report contains maps, figures, and tables that will aid the reader in understanding various components of the text.

APPENDICES

The report has several appendices that contain detailed support data used in compiling the report. This material will provide clarification to the reader by providing additional information or further research within the study area. Appendix A contains the sponsor list and contact information for agencies and groups to help implement the alternatives listed in this river basin study. The letters of request for the study are on file with the

Water Resources Staff of the Natural Resources Conservation Service in Alexandria, Louisiana. Biological Resources such as species of fish, birds, plants and the Christmas Bird Counts in the study area can be found in Appendix B. Appendix C contains contact information for agencies and groups to help implement the alternatives listed in this river basin study. Appendix D contain resource maps of the refuges, the water quality monitoring stations, watershed units, and the oil and gas well locations in the study area. A list of prior studies, reports, and existing water projects can be found in Appendix E.

PHYSICAL SETTING

LOCATION AND SIZE

The study area encompasses 704,253 acres in portions of Caddo, De Soto, Red River, Sabine, and Natchitoches Parishes Louisiana (Figure 1). The project boundary is further defined by beginning at the confluence of Bayou Pierre and the Red River in Natchitoches Parish proceed Northwesterly along the levee system on the west bank of the Red River through Red River Parish and into Caddo Parish, roughly to Interstate 20. Proceed in a Southwesterly direction going into east Texas at a point just north of the Bethany Community in Caddo Parish taking in the Boggy Bayou Watershed. Return in a southeasterly direction re-entering Louisiana south of Bethany Community and then to Kickapoo Community in De Soto Parish. Follow the ridge south through De Soto Parish that divides the Red River and Sabine River Watersheds going through Mansfield and Pelican. Staying on the ridge in a Southerly direction enter Sabine Parish going through Pleasant Hill, Belmont, and Fort Jesup. Turn in a northeasterly direction and enter Natchitoches Parish going between Robeline and Hagewood then North of Sibley Lake Watershed. Return to the point beginning at the confluence of Bayou Pierre and Red River.

The major urban areas within the study area are Shreveport and Mansfield. In addition there are numerous small settlements and communities within the project area. The general drainage pattern that exists in the study area is from the north to south. Bayou Pierre is the initial drainage outlet for most of the area and it outlets into the Red River in the vicinity of Powhatan, Louisiana.

CLIMATE

The climate of the study area is influenced principally by its subtropical latitude, the huge landmass to the north, and the proximity of the warm waters of the Gulf of Mexico. In summer the prevailing southerly winds provide a moist climate, but occasionally the pressure distribution is such as to bring west or north winds and hot dry weather. In winter the area is alternately subjected to moist tropical air and cold dry air. As such, winter temperature fluctuation can be rather extreme in a short time frame.

The relative humidity is 60 percent or more approximately 72 percent of the time and less than 40 percent only 7 percent of the time. There is a chance that the temperature will fall below 20 degrees Fahrenheit (°F) or –7 degrees Celsius (°C) or lower on one or more days in 9 out of 10 years. Temperatures of 32 °F (0 °C) or lower occur on an average of 43 days a year, and temperatures of 90 °F (32 °C) or higher occur on an average of 103 days a year. There is a 50 percent chance of a freeze after March 26th in the spring and before November 8th in the fall. There is a 20 percent chance of a freeze after April 4th in

Bayou Pierre Cooperative River Basin Study

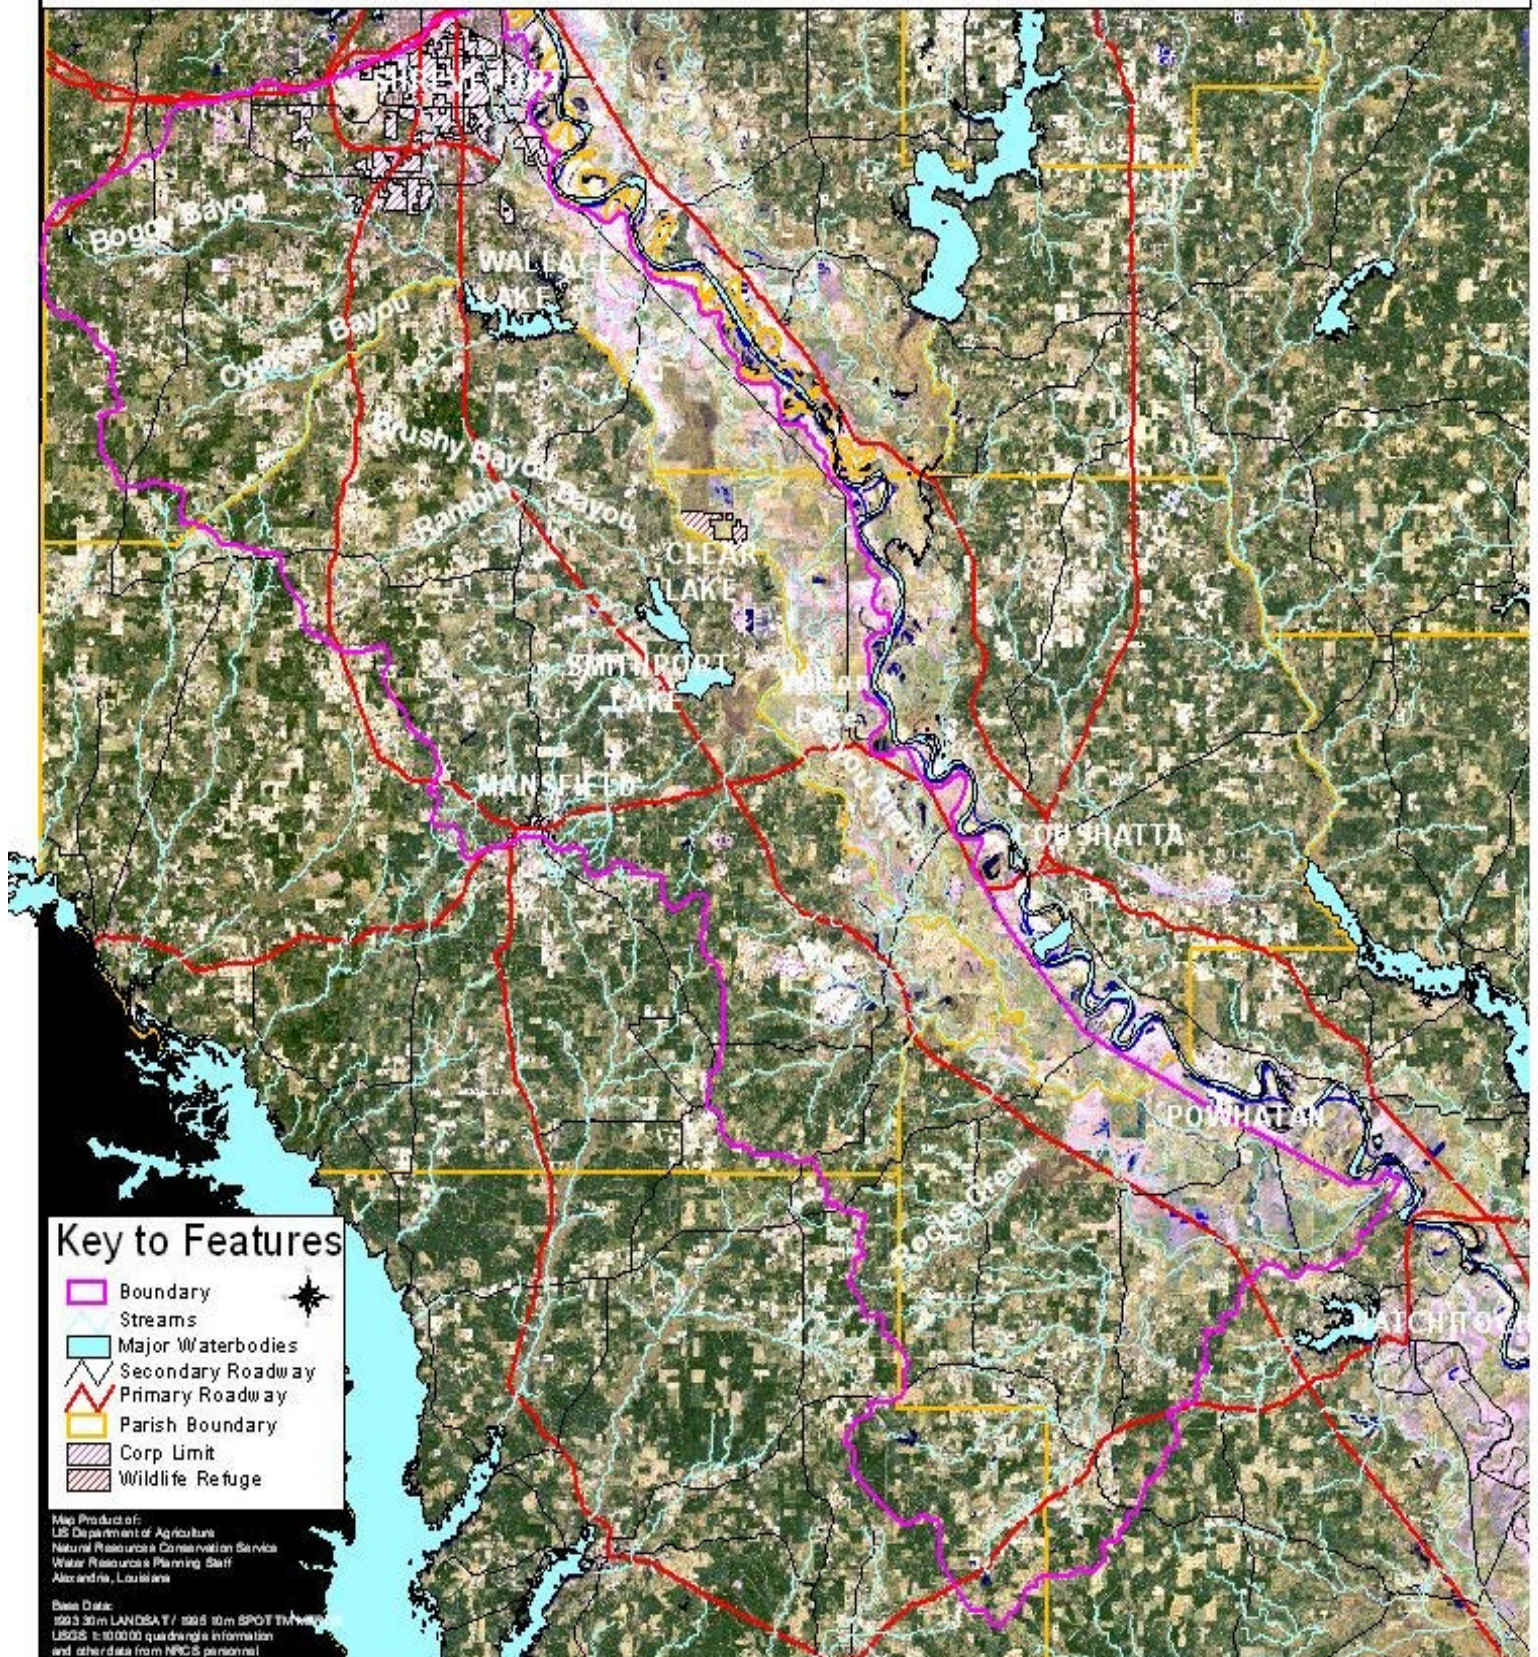

Figure 1

the spring and before October 27th in the fall. The average frost-free period is approximately 222 days a year according to the NRCS Soil Survey.

The average temperature for the year is approximately 66 °F (19 ° C) with extremes on record of a maximum of 114 °F (46 °C) and a minimum of -14 °F (-26 °C). The annual average precipitation is approximately 48.5 inches or 116.3 centimeters (cm) with an extreme minimum and maximum of 30.24 inches (76.8 cm) and 78.91 inches (200.4 cm) respectively.

TOPOGRAPHY AND GEOLOGY

The study area is in the upper part of the Gulf Coastal Plain. The relief is nearly level to gently sloping. Elevations within the study area range from approximately 200 feet National Geodetic Vertical Datum (NGVD) in the northern reaches to 140 feet NGVD in the south. Dominant physiographic features include oxbow lakes, bayous, swamp, natural levees, and abandoned streams.

The study area is included within the Red River Valley which may be divided into an alluvial section underlain by materials deposited by the Red River during the Pleistocene or Glacial period; and a marginal layer underlain by Tertiary and older rocks (USACE 1950). The alluvial geology has a more pronounced influence on the problems within the study area and as such, will be discussed in more detail.

The Red River Valley is entrenched into the Midway Group of the Paleocene series of the Tertiary System. Pleistocene and Recent Age sediments have been deposited in the valley (USACE 1976). The hydraulic connection of the Red River to the Mississippi River was the driving force in the formation of the entrenched valley and is associated with glaciation. The formation was not caused by the migration of the actual ice masses but the subsequent runoff associated with the thawing of the ice. During glacial stages the sea level fell, which in turn, increased the gradient of the streams and prompted the cutting of the entrenched valleys (USACE 1949). During the interglacial stages when the ice masses were melting the gradients became less steep due to sea level rise and caused the valley to be filled with sediments carried by the river. The present valley fills exhibits a similar gradation of fill material from coarse to finer materials. These sediments deposited within these glacial periods are now overlain by alluvial deposits resulting from the overflow of the Red River.

The floor of the entrenched valley is highly irregular and within the study area is near 75 feet deep. The shape of the valley is steep sided with a shelf-like floor gently sloping to the deepest part of the trench. The deepest portion usually has a small V shape that marks the position of the flow of the channel in glacial times of steep gradients when degradation was at its greatest. There are areas that occur within the valley where the ancient materials are at or near the surface and are surrounded by the Recent sediments to form "islands". The sediments that form the floor of the entrenchment are a firmer and

more erosion resistant material of the Tertiary age than the overlying clays, silts, sands, and gravel of the Recent alluvial material (USACE 1950).

The Red River has meandered throughout the valley during the Recent period. The width of meander within the Red River Valley is approximately 2 miles. Since the final removal of the Red River Raft in 1873, the Red has been in or near its present day location. However, prior to the removal of the Raft the channel meandered through bayous that are adjacent to the River.

HISTORICAL AND ARCHAEOLOGICAL RESOURCES

Northwestern Louisiana was occupied for thousands of years before European settlement. In the upland areas, along small streams and bordering the river valleys, projectile points and tools of early and late Paleo-Indian peoples have been found (Webb 1948b; Gagliano and Gregory 1965). The oldest campsites in the Caddo area of northwestern Louisiana are those of the San Patrice culture, thought to date between 8000 and 6000 BC. This culture, which some students look upon as late Paleo-Indian and others as early Archaic, was named for a stream in De Soto and Sabine parishes (Webb 1946).

The first widespread occupation of northwestern Louisiana by pottery making, farming people was that of Coles Creek culture. This culture developed along the lower Mississippi Valley, in Louisiana and Mississippi, including the Lower Red River, starting about AD 700.

The Caddo Indians were the aborigines of Caddo Parish. The Caddo Indians are the principal southern representatives of the great Caddoan linguistic family, which include the Wichita, Kichai, Pawnee, and Arikara. Their confederacy consisted of several tribes or divisions, claiming as their territory the whole of lower Red River. The number of tribes formerly included in the Caddo Confederacy can not now be determined. Only a small number of the Caddo survive, and the memory of much of their tribal organization is lost. One tribe division that exists today in the study area is the Caddo Adais Indians, Inc. The Adai village was located on a small creek near the present town of Robeline, Louisiana, about twenty-five miles west of Natchitoches. The Adais Indians of the Caddo Indian Nation were mostly farmers. This was also the site of the Spanish Mission, Los Adaes. The first historical mention of the Adai was made by Cabeza de Vaca, who in his "Naufragios", referring to his stay in Texas, about 1530, called them Atayos (Glover 1932).

One of the most important cultural sites is near Gahagan located on the west side of the Red River, almost equidistant between Natchitoches and Shreveport. Formerly it was situated on an old channel but much of the channel and site have been destroyed by river caving.

Many other small settlements of earlier times are known to have existed in the study area but have not been studied as extensively as the Gahagan site, 30 to 40 altogether between Natchitoches and the Arkansas state line (Thomas Campbell and Ahler 1977 Webb

1975). These sites are found in the Red River Valley, on lateral lakes and streams, and in the uplands. Apparently, the occupants of these lesser sites were simple farming, gathering, hunting, and fishing folk who did not share in the exotic materials of the complex regional centers. They probably did participate in ceremonies, festivities, and renewals of faith by visits to the centers and may exchange for leadership and protection.

One of the Civil War's bloodiest battles west of the Mississippi took place in Mansfield, Louisiana on April 8, 1864. The Mansfield battlefield was also known as the Sabine Cross-Roads and Pleasant Grove Red River Campaign. The intent of this battle was to capture Shreveport. By this time, Major General Nathaniel P. Banks's Red River Expedition had advanced about 150 miles up Red River. Major General Richard Taylor without any instructions from his commander, Gen. E. Kirby Smith, decided that it was time to try and stem this Union drive. He established a defensive position just below Mansfield, near Sabine Cross-Roads, an important communications center. On April 8, 1864, Banks' men approached, driving Confederate cavalry before them. For the rest of the morning, the Federals probed the Rebel lines. In late afternoon, Taylor, though outnumbered, decided to attack. His men made a determined assault on both flanks, rolling up one and then another of Banks's divisions. Finally, about three miles from the original contact, a third Union division met Taylor's attack at 6:00 p.m. and halted it after more than an hour's fighting. That night, Taylor unsuccessfully attempted to turn Banks's right flank. Banks withdrew but met Taylor again on the 9th at Pleasant Hill. Mansfield was the decisive battle of the Red River Campaign, influencing Banks to retreat back toward Alexandria (National Park Service 2002).

After the Battle of Pleasant Hill on April 9, 1864, Brig. Gen. Tom Green led his men to Pleasant Hill Landing on the Red River, where, about 4:00 p.m. on April 12, 1864, they discovered grounded and damaged Union transports and gunboats, the XVI and XVII army corps river transportation, and U.S. Navy gunboats, with supplies and armament aboard. Union Brig. Gen. Thomas Kilby Smith's Provisions Division, XVII Corps, troops, and the Navy gunboats furnished protection for the army transports. Green and his men charged the boats. When Green attacked, Smith's men used great ingenuity in defending the boats and dispersing the enemy. Hiding behind bales of cotton, sacks of oats, and other obstructions. In the attack, Green was killed. The Confederates withdrew and most of the Union transports continued downriver (National Park Service 2002).

Fort Jesup State Historic Site is an 1850's American military installation. The 21-acre site has a museum, picnic pavilion, trails and an historic kitchen building from the 1850's.

Fort St. Jean Baptiste State Historic Site is a reconstruction of a 1732 French fortification. The 7-acre site has an entire reconstruction of the original timber fort, interpretive signage, and a museum will be completed soon.

INVENTORY OF EXISTING RESOURCES

SOILS

Within the study area most of the soils originated from one of three kinds of parent material: Gulf Coastal Plain sedimentary deposits, old alluvium deposited chiefly by an ancestral Red River, and recently deposited Red River Alluvium.

The Gulf Coastal Plain sedimentary deposits consist of beds of material that ranges in texture from sand to clay. They are generally acid and highly leached. They are old deposits of Tertiary age laid down in former extensions of the Gulf of Mexico.

The old alluvium from which the extensive stream terraces formed is of Pleistocene age. Sandy, permeable, old natural levee deposits have been leached and are commonly acid. The clay is dominantly montmorillonite. Fine textured parent material of this type is less thoroughly leached, is generally high in bases, and contains clay dominated by montmorillonite. Stratification, typical of alluvial sediments, is a common feature.

Recent Red River alluvium consists primarily of water-laden sediments derived from the Reddish Prairie soils of western and central Oklahoma and northwestern Texas. Along the eastern side of the Red River floodplain the parent material has been influenced locally by sediments derived from Coastal Plain soils and deposited by tributary streams. Typically, the alluvium from the Red River is reddish brown in color and alkaline or calcareous in reaction.

All of the alluvium has been laid down by river water. Before manmade levees were built, the river overflowed its channel during flood stage and water spread over the floodplain. The coarser sediments carried in suspension were dropped in bands parallel to and near the channel. These low ridges, consisting of fine sand and silt are known as natural levees. When the flood receded and left water standing in the lowlands, the finest sediments, of clays, settled out. These slack-water clays do not settle until the water is still.

The simple pattern of coarser sediments near the channel and fine sediments in the slack-water lowlands is common along the Red, as well as near old abandoned river courses in the floodplain. Over the centuries, the Red River has meandered back and forth across much of the floodplain. Many old abandoned cutoffs and oxbow lakes are left as evidence of former courses. Sometimes natural levees laid down earlier have been cut out, sometimes sandy sediments have been deposited on top of slack-water clays. Thus, the normal pattern of sediment distribution from a single channel has been partly or completely destroyed in many places, and beds of alluvium of widely contrasting textures may be superimposed. Since the construction of the manmade levee system that parallels the present channel, the flooded area has been greatly reduced.

The locations of the major soil associations within the study area can be found in their descriptions in Figure 2. Narratives of the soil associations are as follows:

Betis - Briley

This map unit consists of gently sloping soils on broad ridgetops and gently sloping to strongly sloping soils on side slopes. Slopes on ridgetops generally are long and smooth and range from 1 to 5 percent. Slopes on Side slopes generally are short and convex and range from 1 to 12 percent. The map unit is about 57 percent Betis soils, 40 percent Briley soils, and 3 percent soils of minor extent. The Betis soils are somewhat excessively drained. The Briley soils are well drained. Most areas of this map unit are used as woodland or pasture. A small acreage is used for homesite development. The Betis soils are moderately well suited to woodland and the Briley soils are also well suited to woodland. The dominant trees are loblolly pine and shortleaf pine. The main concerns in producing and harvesting timber are restricted use of equipment and seeding mortality caused by the sandy texture and droughtiness. Trafficability is poor when the surface layer is dry.

Bowie – Ruston

This map unit consists of soils on convex ridgetops and side slopes in the uplands. The landscape consists of broad or narrow ridgetops and gently sloping side slopes. This map unit is about 60 percent Bowie soils, 23 percent Ruston soils, and 17 percent soils of minor extent. The Bowie soils are moderately well drained and gently sloping. Most areas are used as woodland. A few small areas are used for pasture or homesite development. These soils are well suited to woodland. Few limitations effect this use.

Briley – Betis – Trep

This map unit consists of gently sloping soils on broad ridgetops and gently sloping to strongly sloping soils on side slopes. The landscape is dissected by deeply incised streams and a well defined, branching drainage system. Slopes on ridgetops generally are long and smooth and range from 1 to 5 percent. Side slopes are generally short and convex and range from 1 to 12 percent. The map unit is about 36 percent Briley soils, 22 percent Betis soils, 12 percent Trep soils, and 30 percent soils of minor extent. The Briley soils are well drained. The Betis soils are somewhat excessively drained, and the Trep soils are moderately well drained. Most areas of this map unit are used as woodland or pasture. A small acreage is used for homesite development. The Briley and Trep soils are well suited to woodland, and the Betis soils are moderately well suited to woodland. The dominant trees are loblolly pine and shortleaf pine. The main concerns in producing and harvesting timber are restricted use of equipment and seedling mortality caused by the sandy texture and droughtiness. Trafficability is poor when the surface layer is dry.

Bayou Pierre Cooperative River Basin Study

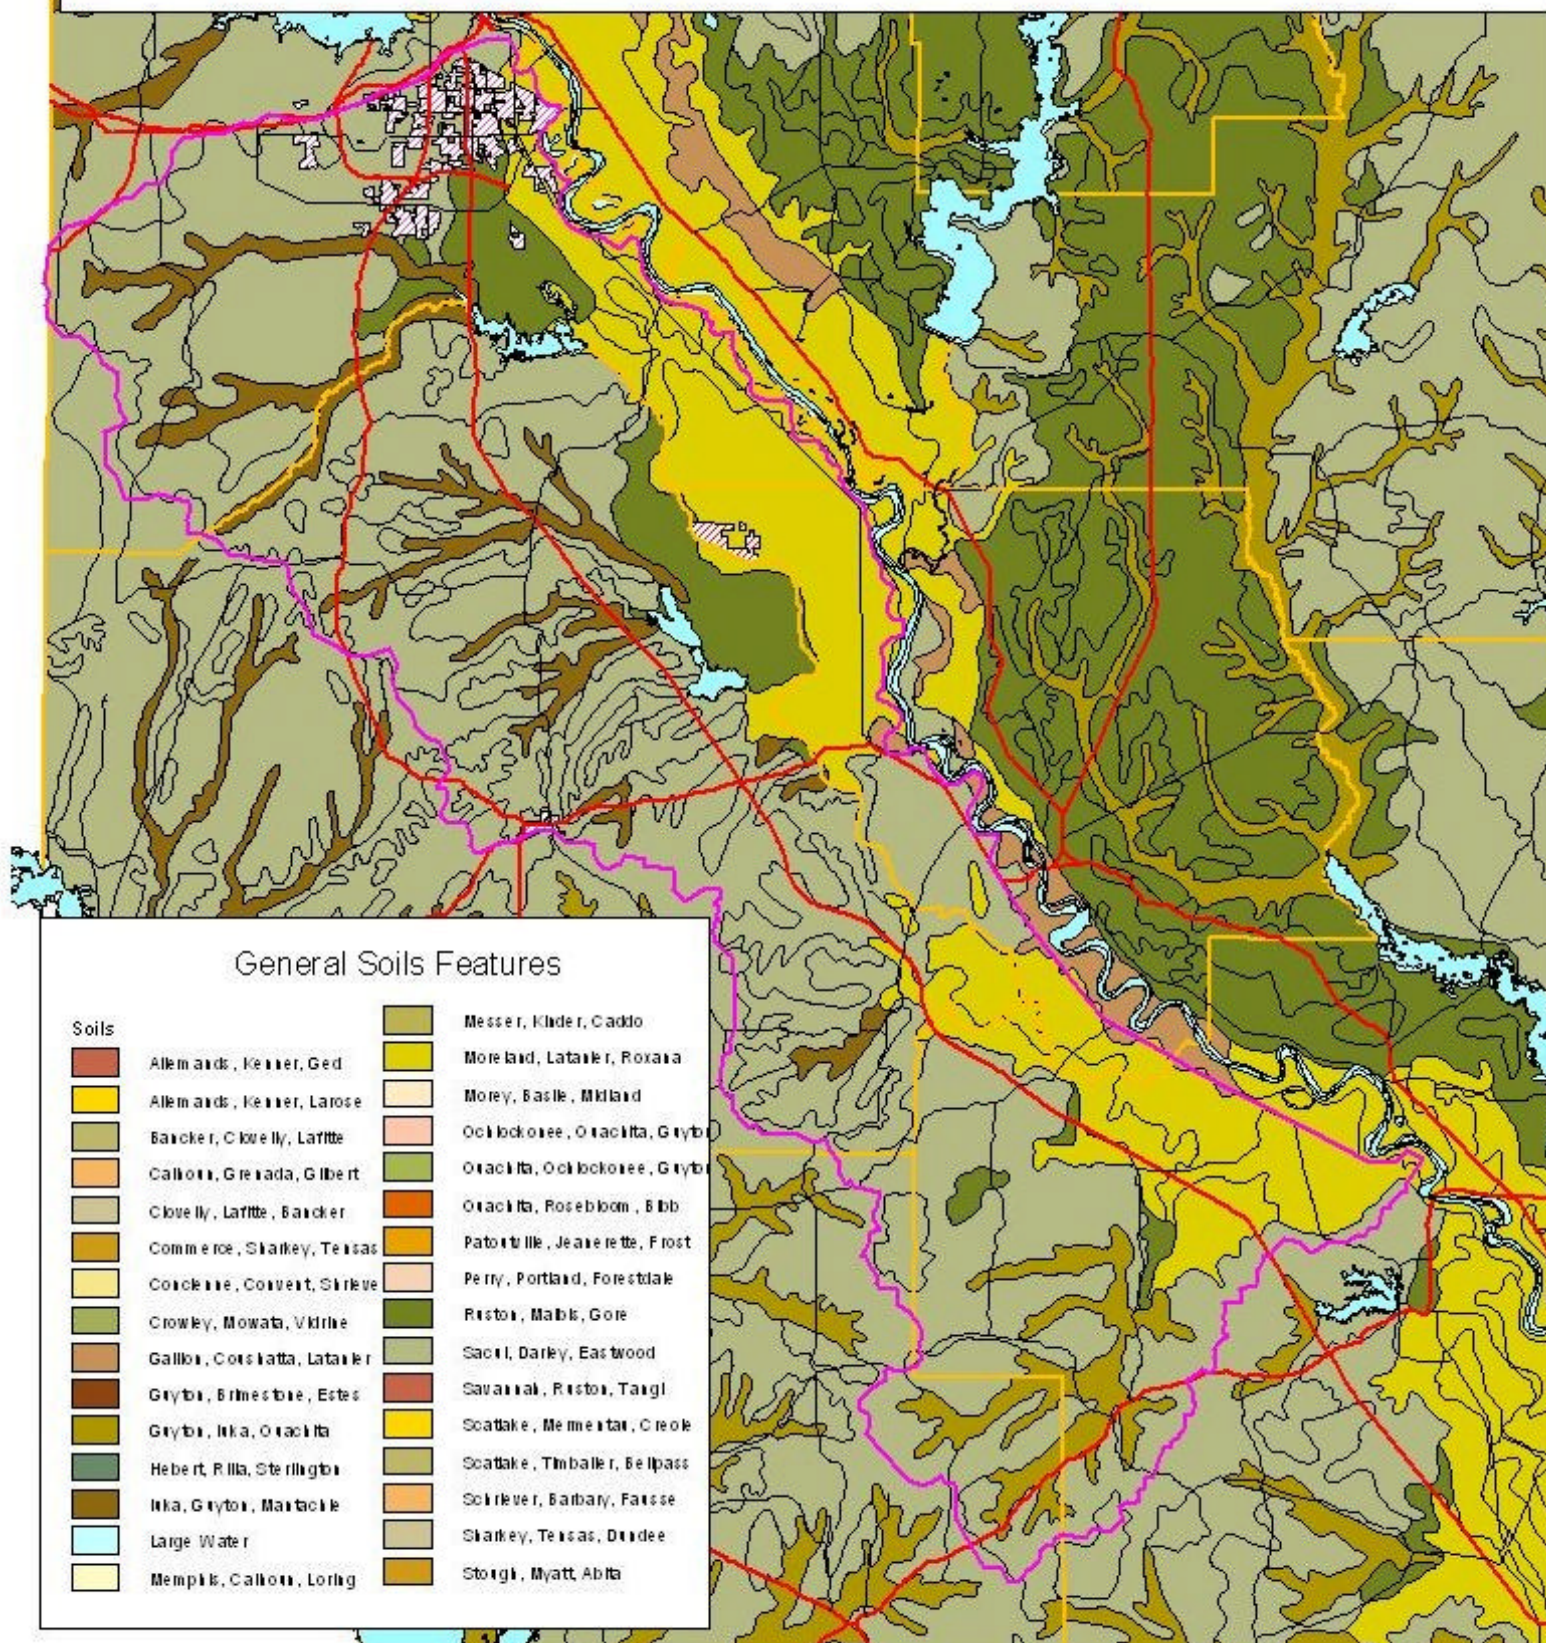

Figure 2

Coushatta – Moreland – Severn

This association consists of soils that are nearly level, well-drained, loamy soils and somewhat poorly drained clayey soils on the Red River alluvial plain. Slopes are mostly less than 1 percent. The map unit is about 52 percent Coushatta soils, 17 percent Moreland soils, 15 percent Severn soils, and 16 percent soils of minor extent. Coushatta soils are loam, well drained, and moderately permeable. Moreland soils are clayey, somewhat poorly drained, and very slowly permeable. Severn soils are loamy, well drained and moderately rapidly permeable. The Coushatta and Severn soils are used mainly for crops, mainly cotton. The Moreland soils are used mainly for pasture and crops, mainly soybeans and grain sorghum. The Coushatta and Severn soils have few limitations for cropland use. The clayey Moreland soils are somewhat difficult to work and they need to be drained.

Eastwood – Keithville – Bowie

This map unit consists of gently sloping soils on narrow to broad ridgetops and gently sloping to strongly sloping soils on side slopes. Slopes on ridgetops range from 1 to 5 percent, and slopes on side slopes range from 1 to 12 percent. The map unit is about 68 percent Eastwood soils, 14 percent Keithville soils, 10 percent Bowie soils, and 8 percent soils of minor extent. The Eastwood soils are moderately well drained and are gently sloping to strongly sloping. The moderately well drained Keithville soils are gently sloping. The moderately well drained Bowie soils are gently sloping to strongly sloping. Most areas of this map unit are used as woodland or pasture. A few small areas are used for homesite development. The soils are well suited to woodland. Loblolly pine, shortleaf pine, sweetgum, southern red oak, and hickory are dominant on the Eastwood soils. Loblolly pine, shortleaf pine, and sweetgum are dominant on the Keithville and Bowie soils. The use of equipment is limited in winter and spring because of wetness. Erosion is a hazard in moderately sloping and strongly sloping areas of the Eastwood soils.

Eastwood – Meth

This map unit consists of soils on convex ridgetops and side slopes in the uplands. The landscape consists of gently sloping ridgetops and moderately sloping and strongly sloping side slopes. Slopes range from 1 to 12 percent. It is about 71 percent Eastwood soils, 14 percent Meth soils, and 15 percent soils of minor extent. The Eastwood soils are moderately well drained and are gently sloping or strongly sloping. The Meth soils are well drained and moderately sloping. They are on the upper parts of the side slopes. Most areas are used as woodland. These soils are moderately well suited to woodland. The main management concern is a moderate equipment limitation caused by the clayey subsoil in the Eastwood soils. Erosion is a hazard along logging roads and skid trails.

Forbing – Gore – Guyton

These soils are on ridgetops, side slopes, and broad flats in the uplands and on broad flats on stream terraces and in drainageways. Slopes range from 0 to 8 percent. The map unit is about 25 percent Forbing soils, 20 percent Gore soils, 19 percent Guyton soils, and 36 percent soils of minor extent. The Forbing soils are moderately well drained and are very gently sloping and moderately sloping. They are on ridgetops and side slopes in the uplands. The Gore soils are moderately well drained and gently sloping. They are also on ridgetops and side slopes in the uplands. The poorly drained Guyton soils are in drainageways and on broad flats in the uplands and on stream terraces. Most areas are used as woodland. These soils are moderately well suited to woodland. In some areas logging activities are limited by wetness during winter and early spring. In the more sloping areas, erosion is a hazard along logging roads and skid trails.

Forbing – Messer – Gore

These soils are on ridgetops, side slopes, and broad flats in the uplands. Slopes range from 0 to 8 percent. This map unit is about 33 percent Forbing soils, 19 percent Messer soils, 16 percent Gore soils, and 32 percent soils of minor extent. Forbing soils are very gently sloping to moderately sloping, moderately well drained, and on side slopes. Messer soils are moderately well drained and are on low, rounded mounds. Gore soils are gently sloping, moderately well drained, and on low ridges or upper parts of side slopes. This map unit is used mainly for woodland. These soils are moderately well suited to woodland. In some areas logging activities are limited by wetness during winter and early spring. In the more sloping areas, erosion is a hazard along logging roads and skid trails.

Gore – Acadia – Wrightsville

In this map unit the landscape has slight to moderate relief. It has convex ridgetops, side slopes, and broad flats and depressional areas on the uplands. This map unit is about 39 percent Gore soils, 24 percent Acadia soils, 21 percent Wrightsville soils, and 16 percent soils of minor extent. The Gore soils are gently sloping, moderately well drained, and are on convex ridgetops and side slopes. The Acadia soils are nearly level, somewhat poorly drained, and are on broad, slightly convex ridgetops. The Wrightsville soils are level, poorly drained, and are on broad flats and in depressional areas. The soils in this map unit are mainly used as woodland. Small acreages are used for pasture or cultivated crops. The soils in this map unit are moderately well suited to use as woodland. The potential productivity of loblolly pine and hardwoods is high. Logging operations during winter and early spring are limited by wet soil conditions. Erosion is a hazard along logging roads and skid trails in the gently sloping areas.

Guyton – Iuka

This map unit consists of soils on narrow flood plains along streams that drain the uplands. Flooding is frequent. It occurs mainly in winter and spring but can occur during

any part of the year. Slopes are less than 1 percent. This map unit is about 64 percent Guyton soils, 13 percent Iuka soils, and 23 percent soils of minor extent. The Guyton soils are poorly drained and on low flats. The Iuka soils are moderately well drained and are on slightly convex natural levees and on microhighs. Most areas of this map unit are used as woodland, which consists of hardwoods or mixed hardwoods and pines. The soils in this map unit are moderately well suited to woodland. Seasonal wetness and flooding limit the use of equipment in winter and spring and cause moderate or severe seedling mortality. The soils easily become compacted if heavy equipment is used during wet periods.

Iuka – Guyton – Mantachie

This map unit consists of soils on narrow flood plains along streams that drain the uplands. Flooding is frequent. It occurs mainly in winter and spring but can occur during any part of the year. Slopes are less than 1 percent. This map unit is about 24 percent Iuka soils, 19 percent Guyton soils, 15 percent Mantachie soils, and 42 percent soils of minor extent. The Iuka soils are moderately well drained and are on slightly convex natural levees and on microhighs. The Guyton soils are poorly drained and are on low flats. The Mantachie soils are somewhat poorly drained and are on low flats. The Mantachie soils are somewhat poorly drained and are on low slightly convex natural levees. Most areas of this map unit are used as woodland, which consists of hardwoods or mixed hardwoods and pines. The soils in this map unit are moderately well suited to woodland. Seasonal wetness and flooding limit the use of equipment in winter and spring and cause moderate or severe seedling mortality. The soils easily become compacted if heavy equipment is used during wet periods.

Keithville – Eastwood

This map unit consists of soils on ridgetops and side slopes in the uplands. Slopes range from 0 to 12 percent. It consists of about 47 percent Keithville soils, 24 percent Eastwood soils, and 29 percent soils of minor extent. The Keithville soils are gently sloping and moderately well drained. They are on narrow or broad ridgetops and gentle side slopes. The Eastwood soils are moderately well drained and are gently sloping or strongly sloping. They are on narrow ridgetops and on side slopes. Most areas are used as woodland. The potential production of pine timber is high. The main management concerns are a moderate seedling mortality rate and a moderate equipment limitation caused by wetness. Erosion is a hazard in the strongly sloping areas.

Keithville – Eastwood – Metcalf

This map unit consists of soils on ridgetops and side slopes in the uplands. The landscape in these areas is one of short, complex slopes on narrow, gently sloping ridgetops and strongly sloping side slopes along deeply incised streams. Slopes range from 0 to 12 percent. This map unit is about 35 percent Keithville soils, 24 percent Eastwood soils, 21 percent Metcalf soil, and 20 percent soils of minor extent. The Keithville soils are gently sloping, moderately well drained, and are on narrow or broad

ridgetops and gentle side slopes. The Eastwood soils are moderately well drained, gently sloping or strongly sloping, and are on narrow ridgetops and on side slopes. The Metcalf soils are somewhat poorly drained, nearly level, and are on broad ridgetops. Most areas are used and are well suited for woodland. The potential for production of pine timber is high. The main management concerns are a moderate seedling mortality rate and a moderate equipment limitation caused by wetness. Erosion is a hazard in the strongly sloping areas.

Keithville – Woodtell – Messer

This map unit consists of soils on broad ridges, in swales, and on side slopes. Slopes range from 0 to 12 percent. It consists of about 31 percent Keithville soils, 24 percent Woodtell soils, 18 percent Messer soils, and 27 percent soils of minor extent. Keithville soils are gently sloping, moderately well drained, and on ridgetops. Woodtell soils are very gently sloping to moderately steep, moderately well drained, and on short side slopes. Messer soils are moderately well drained and on low, circular mounds. This unit is used mainly for pasture and woodland. The potential for pasture is fair. The potential for producing and harvesting timber is good for the Keithville and Messer soils but fair for the Woodtell soil. The main limitations of the Woodtell soil of timber production are moderate growth rates, moderate seedling mortality, and moderate equipment limitations.

Moreland – Armistead – Caspiana

This map unit consists of soils on the lower parts of the natural levees of the Red River and its tributaries. Slopes range from 0 to 1 percent. It consists of about 44 percent Moreland soils, 13 percent Armistead soils, 13 percent Caspiana soils, and 30 percent soils of minor extent. Moreland soils are somewhat poorly drained and are at the lower elevations. Armistead soils are also somewhat poorly drained and are at slightly higher elevations than the Moreland soils. The Caspiana soils are well drained and are on the higher parts of the landscape. This unit is used mainly for cultivated crops and pasture. The main limitations are wetness and the clayey surface textures of the Moreland and Armistead soils.

Moreland – Latanier – Armistead

In this map unit, the landscape typically has very little relief. It is mainly broad flats, natural levees, and backswamps on the Red River alluvial plain. Slopes are generally less than 1 percent, but can range from 0 to 3 percent along narrow channel scars. It consists of 55 percent Moreland soils, 32 percent Latanier soils, 8 percent Armistead soils, and 5 percent soils of minor extent. All of these soils are somewhat poorly drained. The Moreland soils are in low positions on natural levees. The Latanier and Armistead soils are in intermediate positions on natural levees. Most areas of the soils in this map unit have been cleared and are used for crops, mainly soybeans and grain sorghum. Small acreages are used as pasture or woodland. The soils in this map unit are moderately well suited to cultivated crops and well suited to pasture. Wetness and poor tilth are the main limitations. A surface drainage system is needed to remove excess water.

Moreland – Severn – Norwood

This map unit consists mainly of broad flats, high natural levees and backswamps on the Red River alluvial plain. Slopes are generally less than 1 percent, but can range from 0 to 3 percent along old channel scars. It consists of 39 percent Moreland soils, 33 percent Severn soils, 19 percent Norwood soils, and 9 percent soils of minor extent. If not protected by the Red River levee systems, these soils are subject to flooding. Moreland soils are somewhat poorly drained and are on lower parts of the landscape. Severn and Norwood soils are well drained and are generally at the highest positions on the landscape. This unit is used mainly for cultivated crops, but a few large tracts on the unprotected side of the levee system are used for pasture. Where protected from flooding, this unit has excellent potential for cultivated crops and has only slight limitations for this use.

Moreland – Yorktown

This map unit is on broad flats and backswamps on the flood plain of the Red River. Slopes are generally less than 1 percent. It consists of 83 percent Moreland soils, 12 percent Yorktown soils, and 5 percent soils of minor extent. The Moreland soils are somewhat poorly drained and are in low positions on natural levees and in backswamps. The Yorktown soils are very poorly drained and are in old stream channel scars and depressional areas. The soils in this map unit are used about equally as cropland and woodland. Most areas of the occasionally flooded Moreland soils have been cleared and are used for cultivated crops or pasture. Soybeans and grain sorghum are the main crops. The frequently flooded Moreland and Yorktown soils are used as woodland for timber production and as wildlife habitat.

Norwood – Roxana – Gallion

This map unit consists of high ridges or natural levees adjacent to the Red River and former channels and distributaries of the Red River. Slopes are 0 to 1 percent. The soils are protected from flooding by a network of levees. It consists of about 57 percent Norwood soils, 17 percent Roxana soils, 13 percent Gallion soils, and 13 percent soils of minor extent. All of these soils are well drained and are on high positions on natural levees of the Red River. Most of the soils in this map unit are used for cultivated crops, mainly cotton, corn, and soybeans. The soils in this map unit are well suited to cultivated crops and pasture. The loamy surface layer, high and medium fertility, and level slopes favor these uses. Wetness is a slight limitation for crops in some areas of the Gallion soils. Land grading or smoothing and a surface drainage system can reduce wetness.

Ruston – Malbis – Smithdale

This map unit consists of soils on uplands and is dominated by narrow to broad, gently sloping ridgetops and strongly sloping and moderately steep side slopes. The landscape is dissected by a well-defined, branching drainage system. Slopes range from 1 to 20

percent. It consists of about 36 percent Ruston soils, 22 percent Malbis soils, 22 percent Smithdale soils, and 20 percent soils of minor extent. The Ruston soils are well drained and are on gently sloping, convex ridgetops. The Malbis soils are well drained and are on gently sloping, convex ridgetops. The Malbis soils are moderately well drained and are on gently sloping, broad ridgetops and on side slopes. The Smithdale soils are well drained and are on strongly sloping and moderately steep side slopes. The soils in this map unit are mainly used as woodland. In many small areas, they are used as pastures or homesites. The soils are well suited to use as woodland. The potential productivity of loblolly pine is high. The soils have few limitations for this use; however, management that minimizes the risk of erosion is needed.

Sacul

This map unit consists of moderately sloping to steep soils on side slopes. Slopes are short and range from 5 to 30 percent. It consists of about 94 percent Sacul soils and 6 percent soils of minor extent. The Sacul soils are moderately well drained. Most areas of this map unit are used as woodland. A few small areas are used as pasture. The moderately sloping and strongly sloping Sacul soils are well suited to woodland, and the moderately steep and steep Sacul soils are moderately well suited to this use. The dominant trees are loblolly pine and shortleaf pine. Because of seasonal wetness, the use of equipment is limited in winter and early spring. Erosion is a hazard along logging roads and skid trails.

Sacul – Kirvin – Keithville

This map unit consists of soils on the narrow to broad ridgetops and side slopes of interstream divides. These soils are dominantly gently sloping but in some areas around the head of small drainageways, are moderately sloping or strongly sloping. Slopes range from 1 to 12 percent. It consists of about 67 percent Sacul soils, 15 percent Kirvin soils, 12 percent Keithville soils, and 6 percent soils of minor extent. The Sacul soils are gently sloping to strongly sloping and are well drained. The Keithville soils are gently sloping and moderately well drained. Most areas of this map unit are used as woodland. The soils in this map unit are well suited to woodland. The dominant trees are loblolly pine, shortleaf pine, and sweetgum. Logging is limited in areas of the Sacul and Keithville soils during winter and early spring because of wetness and the clayey subsoil.

Sacul – Larue – Mahan

This map unit is in the uplands and consists of narrow ridgetops and moderately sloping to steep side slopes along deeply incised streams. Slopes range from 1 to 12 percent. It consists of about 60 percent Sacul soils, 24 percent Larue soils, 5 percent Mahan soils, 11 percent soils of minor extent. The Sacul soils are moderately well drained and are gently sloping, strongly sloping, or steep. The Larue soils are well drained and are gently sloping. They are on ridgetops and on the upper parts of side slopes. The Mahan soils are well drained, are gently sloping or moderately sloping, and occur on ridgetops. Most areas are used as woodland. A few small tracts are used for pasture or homesite

development. These soils are moderately well suited to woodland. The main limitations are droughtiness in the Larue soils and the hazard of erosion on the steep Sacul soils.

Severn – Moreland – Roxana

This map unit consists mainly of broad flats and high natural levees and back swamps on the Red River alluvial plain. Slopes are generally less than 1 percent, but can range from 0 to 3 percent along old channel scars. It consists of about 88 percent Severn soils, 7 percent Moreland soils, 3 percent Roxana soils, and 2 percent soils of minor extent. If not protected by the Red River levee system, these soils are subject to flooding. Severn and Roxana soils are well drained and are generally at the highest positions on the landscape. The Moreland soils are somewhat poorly drained and are on lower parts of the landscape. This unit is used mainly for cultivated crops, but a few large tracts on the unprotected side of the levee system are used for pasture. Where protected from flooding, this unit has excellent potential for cultivated crops and has only slight limitations for this use.

WATER RESOURCES

The study area has an adequate supply of water available for agricultural, municipal, industrial, and domestic use. Both ground and surface water are used to meet these consumptive demands. For Caddo Parish the total water use has ranged from .38 million gallons per day (Mgal/d) to 92.39 (Mgal/d). In De Soto Parish, the total water use range from .12 to 16.97 Mgal/d. Natchitoches parish water use ranges from .49 to 12.69 Mgal/d. The water use in Red River Parish ranges from .01 to .74 Mgal/d. Natchitoches Parish has water use ranging from .49 to 12.69 Mgal/d. Sabine Parish has a water use that ranges from .02 to 2.39 Mgal/d. In Red River Parish the water consumption for the period of 1960 – 1990 ranged from approximately 0.75 Mgal/d to about 2 Mgal/d with an extreme of approximately 7.5 Mgal/d in 1975 (Lovelace 1990).

Surface Water

The principal source of surface water for the study area is the Red River. The average discharge of the Red River for a period of 1928-75 was 24,900 cubic feet per second. During summer months the flows within the Red River are usually at the lowest. Maximum sediment discharge usually occurs during May. There has been a decrease in the concentrations of dissolved solids, chloride, and sulfates. However, high concentrations of chloride and sulfate have been a problem in the past, especially during low flow events. The majority of high levels of chloride can be attributed to inflow from the Texas and Oklahoma regions of the Red River Basin.

In the Rivers and Harbors Act of 1968, Congress authorized the U.S. Army Corps of Engineers to construct the current Red River Waterway project. The plan specified five lock and dam structures in Louisiana between Avoyelles Parish near Marksville and the Shreveport-Bossier area. The Red River Navigation Project provides a channel nine feet deep and 200 feet wide from the mouth of the river to Shreveport and Bossier City. The

total distance of that part of the river was reduced by 50 miles as a result of channel realignments for shipping convenience. An added benefit, these realignments straighten out bends in the river, leaving behind beautiful oxbow lakes, suitable for excellent recreational developments. Included in the Red River Master Plan for Recreation, many of these areas, as well as thousands of acres of other riverfront properties, have designated as locations for extensive land and water sports facilities (Red River Valley Association).

While the aforementioned changes have benefited some user groups and some species of fish and wildlife, that alteration of riverine habitat may have adversely impacted other resources and users. Creation and/or maintenance of vessel and vehicular access will be required to ensure that the public will be able to utilize the oxbows created through channelization. Frequent management and maintenance of those oxbow lakes must be conducted to reduce high rates of sedimentation and prolong their recreational values. Additionally, the development of recreational properties along those oxbows can be expected to reduce the amount of bottomland forest habitat in the area and contribute to nonpoint source pollution to those water bodies (US Fish & Wildlife Service).

A project that could pave the way for future utilization of the Red River as a source of irrigation water is the Red Bayou Irrigation Project. This project is located in northeast Caddo Parish and is about 13,800 acres in size. The project is in the early plan development. Preliminary surveys have indicated that it would be possible to construct a pump station in the Red River for the purpose of moving irrigation water from the river into Red Bayou. One or more weirs would have to be constructed in the channel of Red Bayou to maintain irrigation pools. Once implemented this project will decrease the demand placed on the limited amount of water in the Red River Alluvial Aquifer.

Figure 3 will depict the surface-water withdrawals for the Red River Basin. The one-page summary includes withdrawals by category of use, by parish, and withdrawals from major water bodies in the Red River Basin. Below the name of the basin is a location map showing the areal extent of the basin (modified from Garrison and Covay 1994). The three tables list withdrawals by category of use and the total withdrawal from surface sources within the basin, withdrawals by parish for the basin, and withdrawal by major water body within the basin.

Groundwater

The two primary sources of ground water within the study area are the Red River alluvial aquifer and the Wilcox-Carrizo Aquifer. A small portion of the study area is underlain by the Sparta Aquifer as well. The alluvial aquifer is the primary source of water for domestic, livestock, and irrigation uses.

The Red River Alluvial Aquifer is the largest and in some cases the only available source of fresh ground water. The aquifer consists of fine to medium sand in the upper part of the deposit to coarse sand and gravel in the lower reaches. The alluvial deposits are about

65 feet deep in the study area and confined by a clay, sandy clay, or silt layer. The aquifer thickness averages about 45 feet within the study area. The alluvial aquifer is the most permeable aquifer in the area. Water in the alluvial is under both artesian and water table conditions. The alluvial aquifer is recharged from infiltration of rainfall; from streams when the stage of the stream exerts a head differential greater than the potentiometric head of the aquifer; and from the under-lying Wilcox-Carrizo aquifer in areas where its potentiometric head is greater than that of the alluvial.

The hardness of the water within the alluvial aquifer ranges from 330 to 560 milligrams per liter (mg/l) with an average of 415 mg/l. The iron concentration ranges from 0.02 to 10 mg/l and averages 5.5 mg/l. The manganese concentration is likely to be relatively higher than 0.05 mg/l, which is the maximum value established in the primary standards of the Safe Drinking Water Act. As such, the alluvial aquifer has the potential for being the primary source of water for public supplies. However, treatment is required to reduce hardness and other minerals within the water (Whitfield 1980). Withdrawals by parish and withdrawals in million gallons per day are shown in Figure 5.

The Carrizo - Wilcox underlies the alluvial deposits within the area. Some of the study area is also in the Red River Alluvial Aquifer. The Carrizo - Wilcox formation is the principal source of public-supply systems within the western fringes of the study area. There are areas within the aquifer where chloride concentrations may exceed 250 mg/l. The typical yield of a well screened in this aquifer will range from 40 to 280 gal/min. The thickness of the aquifer generally ranges from 280 to 390 feet in thickness with the water-producing lens of sand averaging approximately 30 feet at various levels within the formation. These waters, producing fine grain sand layers, are deposited in layers that are broken by confining beds of clay or lignite. The thickness of the water producing sands can vary significantly within a short horizontal distance. Due to the variability in sand thickness, it is usually necessary for several test holes to be drilled before an adequate sand can be found.

The Sparta is pumped in a large area of north central Louisiana and in a narrow band through the project area covering Natchitoches and Sabine parishes. Groundwater movement is eastward toward the Mississippi River Valley and southward toward the Gulf of Mexico, except when altered by heavy pumping, and the hydraulic conductivity varies between 25 to 100 feet/day. The maximum depths of occurrence of freshwater in the Sparta range from 200 feet above sea level, to 1,700 feet below sea level.

Withdrawals from the Carrizo - Wilcox aquifer by parish and withdrawals in million gallons per day is shown in Figure 4. Withdrawals from the Red River Alluvial Aquifer are shown in Figure 5. The Sparta Aquifer is depicted in Figure 6.

Groundwater Rights in Louisiana

Groundwater may be defined as fresh water situated beneath the land but within 2500 feet of the surface; it is a natural resource very often taken for granted. Although Louisiana's groundwater law is not clear, we are generally considered an absolute ownership state. The State of Louisiana has recognized that the economic development and well-being of the state is inextricably connected to the use of freshwater from the state of Louisiana's surface and aquifer sources. As a result, Executive Order Governor Murphy J. Foster 00-44 created Louisiana State Water Policy Advisory Task Force. Article 490 of the Louisiana Civil Code seems to be consistent with the absolute ownership law by stating that a landowner owns everything on, above or below his land. However, in respect to groundwater, the courts have interpreted this article to mean that a landowner does not have absolute ownership, but only owns the water after he has captured it.

Article 667 says that although a landowner may do with his estate whatever he pleases, still he cannot harm his neighbor. This article appears to restrict absolute ownership, but it is questionable as to whether or not this Article can be applied to the use of groundwater. Along with these Article, the Mineral Code also addresses the ownership of groundwater. The Mineral Code treats groundwater as a mineral and goes along with the court's interpretation of Article 490 saying that a landowner does not actually own the water below his land but only owns it once he has pumped it out of the ground.

Constitutional Amendment 10, known as the Groundwater Conservation amendment was included on Louisiana November 5, 2002 Election Ballot. The amendment was sponsored by Senator Max Malone , R-Shreveport during the 2001 Regular Session. The passage of this amendment would authorize the Louisiana Legislature to create programs to provide loans, grants and other subsidies to farmers who voluntarily forgo irrigating with groundwater in periods of drought. It would also assist those in agriculture in developing other water resources for irrigation. The amendment failed with the results being 46 percent for, and 54 percent against.

Surface Water Monitoring

The Louisiana Department of Environmental Quality Office of Water Resources surface water monitoring program is intended to measure development towards achieving water quality goals at the state and national levels and to gather baseline data used in establishing and reviewing the state water quality standards, thereby providing a database for use in determining the assimilative capacity of the waters of the state. Information is also used to establish permit limits for wastewater discharges.

The surface water-monitoring program consists of a fixed station long-term network, intensive surveys, individual studies, and wastewater discharge compliance sampling. LDEQ and its forerunner agencies have maintained a surface water quality-monitoring program since the 1950's. This program has consisted of collecting water samples from designated points on waters across the state on a monthly or bimonthly basis. These samples are analyzed for 23 different chemical parameters and for bacteria. The purpose

of such a program is to provide baseline or background data on a water body and to monitor long-term trends in water quality. Over the years, monitoring stations have been discontinued or added as needs or conditions changed. Samples collected monthly, or bimonthly, from the stations are analyzed in the LDEQ laboratory using procedures detailed by the state and the Environmental Protection Agency approved Quality Assurance Plan.

Parameters monitored under the monthly ambient surface water quality network for LDEQ include pH, temperature, dissolved oxygen, salinity, alkalinity, hardness, turbidity, conductivity, sulfates, true color, chlorides, total Kjeldahl nitrogen, total dissolved solids, total suspended solids, arsenic, cadmium, chromium, copper, mercury, lead, nickel, nitrate, and nitrite N., total phosphorous, total organic carbon, and coliform bacteria.

Designated Uses of Water Bodies

Each sub-segment in the river basin has been assigned certain designated uses by LDEQ. The Clean Water Act requires that these designated uses be maintained. Both numerical and non-numerical criteria have been established for each of these use categories. Support of designated uses is based upon frequency of exceedances of water quality criteria. In general, the main criteria considered in the determination of use attainment are: Primary Contact Recreation – fecal coliform bacteria - 400/100 ml; Secondary Contact Recreation – fecal coliform bacteria – 2000/100 ml; Fish and Wildlife Propagation – dissolved oxygen – 5 mg/L (fresh water); Public Water Supply – total coliform bacteria – 10,000/100mL, fecal coliform bacteria – 2000/100 ml. The designated uses are as follows:

1. Primary Contact Recreation (PCR) – All sub-segments
2. Secondary Contact Recreation (SCR) – All sub-segments
3. Fish and Wildlife Propagation (FWP) – All sub-segments
4. Agriculture (AGR) – All sub-segments
5. Outstanding Natural Resources (ONR)

Water Quality Stations

US Geological Survey Monitoring Stations

Four stations in the Bayou Pierre River Basin are currently monitored by the United States Geological Survey (USGS) Office. A map of these monitoring stations is contained in Appendix D. These sites are located in hydrologic unit 11140206 that is included in the Watershed Unit Map shown in Appendix D also. These four stations are:

1. Bayou Pierre at Shreveport, LA (07350700)
2. Cypress Bayou Near Keithville, LA (07351500)
3. Bayou Pierre Near Lake End, LA (07351750)
4. Bayou Pierre at Powhatan, LA (07351755)

Bayou Pierre at Shreveport, LA (07350700) is located at Latitude 32°27'20", Longitude 93°44'06", Caddo Parish, at bridge on East 70th Street, 1.5 miles east of Interstate 49 on Hydrologic Unit 11140206. This station has a drainage area of approximately 14.2 square miles.

Cypress Bayou Near Keithville, LA (07351500) is located at Latitude 32°18'00", in Southwest SW ¼ section 8, Township 15 North, Range 14 West, Caddo Parish on Hydrologic Unit 11140206 on downstream side of bridge on U.S. Highway 171, immediately downstream from Texas and Pacific Railroad bridge, 2.0 miles south of Keithville, and 6.0 miles upstream from mouth of Boggy Bayou.

Bayou Pierre Near Lake End, LA (07351750) is located at Latitude 31°53'40", in E ½ sec. 36, T.11 N., R. 10 W., Natchitoches Parish, Hydrologic Unit 11140206, near right bank on downstream side of bridge on State Highway 174, ½ mile downstream from Jims River, and 2.9 miles southwest of Lake End.

Bayou Pierre at Powhatan, LA (07351755) is located at Latitude 31°51'37", Longitude 93°12'22", Natchitoches Parish, at bridge on State Highway 485, 1.0 miles southwest of Powhatan, and 11.8 miles upstream from mouth. The drainage area is 879 square miles.

Louisiana Department of Environmental Quality Monitoring Stations

The Louisiana Department of Environmental Quality (LDEQ) maintains 4 monitoring sites in the Bayou Pierre Study area. According to LDEQ most of the sites only have data through May of 1988, which is when the 5 year rotating basin plan came into effect. For the year 2002, the Red River Basin is being sampled intensively. All of the sites are located in subsegments 100601-100606. The newer sites (0983 and up) were recently assigned for the 2002 sampling survey. Some of the older sites will have been picked up again in 2002. Site 0143 only had data through 1989 due to the fact that this site was replaced by two other sites on Bayou Pierre. A map of the monitoring sites is located in Appendix D. Site 0143 only had data through 1989. The site numbers, names, and locations are as follows:

Bayou Pierre near Lake End, Louisiana (100606, site no. 0143) located at bridge on State Hwy 174, 0.5 miles downstream from mouth of Jims River and 2.9 miles southwest of Lake End. Data on this site has been collected from January 12, 1987 to December 12, 1989.

Bayou Pierre west of Grand Bayou, Louisiana (100606, site no. 0277) located at U.S. Highway 84 bridge, 0.7 miles upstream from Bailey Bayou, 2.8 miles west of Grand Bayou, Louisiana. Data on this site has been collected from January 8, 1990 to May 11, 1998.

Bayou Pierre near Shreveport, Louisiana (100601, site no. 0278) located at State Highway 526 bridge, 0.75 mile northeast of Forbing, Louisiana 8.0 miles south of Shreveport, Louisiana.

Brushy Bayou near Shreveport, Louisiana (100603, site no. 0279) located at Louisiana Highway 526, 8.25 miles south of Shreveport, Louisiana.

Cypress Bayou south of Shreveport, Louisiana (100603, site no. 0280) Cypress Bayou at Linwood Avenue, 12 miles south of Shreveport, at Caddo-De Soto Parish line, Louisiana.

Clear Lake north of Mansfield, Louisiana (100605, site no. 0281) located at Louisiana Highway 509, 10.25 miles north of Mansfield, Louisiana, Clear (Edwards) Lake/Smithport Lake.

Degree of Support of the Surface Water Bodies

Results of ambient surface water monitoring are used to determine if water bodies are meeting their designated uses. All site-specific data is available from LDEQ, and can be easily obtained from their website www.deq.state.la.us/planning/305b/1998/305b-atab10.htm. For 1998, the following degrees of support were listed:

1. 100606 – Insufficient Data
2. 100601 - Not Meeting Its Designated Use
3. 100603 - Not Meeting Its Designated Use
4. 100605 - Threatened
5. 100602 - Insufficient Data

Suspected Sources and Causes of Water Impairment

The following includes all of the suspected causes and sources in the Bayou Pierre River Basin according to the 1998 LDEQ 305b Report.

<u>Suspected Causes</u>	<u>Suspected Sources</u>
Organic Enrichment/Low Dissolved Oxygen	Unknown
Pathogen Indicators	Unknown
Metals	Unknown
Cadmium	
Lead	
Mercury	
Copper	

Total Maximum Daily Load

Section 303(d) of the 1972 Clean Water Act (CWA) requires all states to develop a list of their state's impaired waterbodies. The 303(d) list of impaired waterbodies consists of those waterbodies that do not meet state regulatory water quality standards even with the current pollution controls in place (even after point sources of pollution have installed the minimum levels of pollution controls). The CWA also requires all states to establish

priority rankings for waters on the 303(d) list and develop Total Maximum Daily Loads (TMDLs) for these waters based on their individual priority ranking.

A TMDL is a pollution budget for a specific waterbody (river, lake, stream, etc.) It is the maximum amount of a pollutant (sum of allowable pollutant loads from point and nonpoint sources) that can be released into a waterbody without causing the waterbody to become impaired and/or violate state water quality standards. A TMDL also must include a margin of safety to allow for any uncertainties in the scientific methods used to derive the TMDL (water quality modeling assumption, etc.)

Point sources originate from a stationary location or fixed facility from which pollutants are discharged directly into a waterbody. Some examples of point sources include:

- Wastewater effluent, both municipal and industrial facilities
- Runoff and infiltration from confined animal feeding operations
- Runoff from active mine sites and oil fields
- Runoff and leachate from waste disposal sites

Pollution sources, which are diffuse and do not have a single point of origin or are not introduced into a receiving stream from a specific outlet, are considered nonpoint sources of pollution. Some examples of nonpoint sources are:

- Runoff from row-crop agriculture (including return flow from irrigated agriculture)
- Runoff from pasture and range
- Runoff from forested areas
- Runoff from roads, highways and parking lots
- Runoff from urban stormwater
- Runoff from lawns and gardens
- Activities on the land that generate pollution, such as logging, wetland conversion for development and construction
- Natural sources, such as leaves, organic nutrients and wildlife feces

Most of the attention about TMDLs has been focused on agriculture and forestry. However, municipalities, urban areas, business and industry, and rural subdivisions are also subject to TMDLs. Municipalities can be affected in three ways. The discharge limits for solids, biochemical oxygen demand (BOD), and nutrients from sewage plants are subject to being lowered, which can be quite expensive to comply with. Urban stormwater may contain high loadings of many types of pollutants including nutrients, fecal coliform bacteria, oil and grease, metals and pesticides.

EPA is under a court order or consent decree in many states to ensure that TMDLs are established. The CWA authorizes the states to develop TMDLs, but if the states do not develop the TMDLs, then EPA must develop them. Region 6 EPA signed a memorandum of understanding (MOU) agreeing to establish 609 TMDLs for 196 waterbodies in Louisiana over a 12-year period. TMDLs for the Red River Basin is scheduled for completion by March 31, 2005.

Drainage Patterns

The Bayou Pierre Study area lies totally within the alluvial plain of the Red River. Before man's intervention, floodwaters regularly flowed over the banks of the Red River into this valley. Floodwater and excess rainfall within the basin were drained by a network of streams running parallel to Red River. These streams and the overall alluvial valley were quite flat and contained many large areas of natural depression. The runoff was quite slow and the land remains inundated for long periods.

The most important obstruction to natural drainage patterns was the construction of a levee system along the Red River. Since its expansion in 1946 this levee has not been breached. Backwater flooding from the Red River is now insignificant. The levee easily retained the 100-year flood of 1990.

Bayou Pierre Operations and Maintenance

According to the US Army Corps of Engineers 1976 Operations & Maintenance report for Bayou Pierre, Louisiana, Public Law 738 was authorized in June 1936 (USACE 1976) . It provided for channel enlargement on Bayou Pierre at intervals extending from the confluence with Bayou Wincey near Hanna, Louisiana, to the confluence with the Red River about 12 miles northwest of Grand Ecore, Louisiana. This reach of Bayou Pierre nearly parallels the general course of the Red River and forms a portion of the southwesterly boundary of Red River Parish. Act 761, the Flood Control Act of 28 June 1938, modified Act 738 and transferred maintenance responsibility from local interest to the Federal Government.

Channel enlargement on Bayou Pierre was distributed over a reach of 12.9 miles at a cost of \$299,529 and was completed in FY 1939. The O&M Plan that was developed consisted of applying herbicides at various stages in the stream to allow for the eradication of noxious broadleaf vegetation that grows over the streambank and the removal of drift and debris that accumulates in the stream and on the various bridge crossings.

The flood control project on Bayou Pierre, vicinity of Shreveport, Louisiana, was authorized by Act of Congress, approved 24 July 1946 according to the April 1950 Corps of Engineers Operation and Maintenance Manual. This project area is located along the upper reaches of Bayou Pierre between Miles 64.7 and 84.87. This Act treated only the lower part of the project relative to which the Caddo Levee District had furnished assurances of local cooperation, and outside the City of Shreveport. The work was initiated on July 28, 1943 and was completed in July 1948. Works of improvement consisted of channel improvement of Bayou Pierre by clearing and snagging from Mile 64.7 to Mile 75.64 and by channel enlargement from 75.64 to Mile 83.26. The Act required that the Caddo Levee District appoint a permanent committee or organization headed by an official who was to be called the "Superintendent." Periodic inspections of the project shall be made by the Superintendent.

The flood control project on Bayou Pierre, vicinity of Shreveport, Louisiana, Shreveport Section was authorized by Congress and approved on July 24, 1946. The Shreveport section consisted of channel improvement of Bayou Pierre and east Bayou Pierre by enlargement from Mile 83.26 to Mile 84.17 and by clearing and snagging above this point to Mile 84.87; of West Branch Bayou Pierre by enlargement from Mile 83.6 to Mile 83.8 and of Ockley Drive Ditch by enlargement from Mile 0.00 to Mile 0.37. Ockley Drive Ditch and West Branch Bayou Pierre have been further improved by means of channel paving.

Work on the Shreveport Section was initiated in October 1948 and completed in March 1949. The City of Shreveport was required to appoint a permanent committee or organization headed by a Superintendent, who was to be in charge of a force responsible for the efficient operation and maintenance of the project.

BIOLOGICAL RESOURCES

Special Emphasis Areas

Special-emphasis areas include the 1, 337-acre Bayou Pierre Wildlife Management Area (WMA) in the Cannisnia Lake area of De Soto Parish, which is owned and managed by the Louisiana Department of Wildlife and Fisheries (LDWF). The Bayou Pierre WMA includes a waterfowl refuge and a dove field adjacent to Bayou Pierre, and an information station and field office; no trapping or fishing is allowed on the refuge portion. There are several tracts in the Bayou Pierre Basin enrolled in the NRCS' Wetlands Reserve Program (WRP) and the U.S. Fish and Wildlife Service's Partners for Fish and Wildlife Program, as well as a former Farmers Home Administration inventory tract incorporated into Bayou Pierre WMA. Of the enrolled properties, only one WRP tract is located near the Bayou Pierre channel and no WRP or Partners tract encompasses the Bayou Pierre riparian zone.

Aquatic Habitats and Fishery Resources

Major water bodies in the study area include Bayou Pierre, the Red River, Wallace Lake, Cannisnia Lake, Clear Lake-Smithport Lake, and Bayou Pierre Lake. Fisheries possibly occurring in the basin can be found in Appendix B. Aquatic habitat include the Bayou Pierre channel and its slackwater areas and floodplain. Much of Bayou Pierre has been affected by channelization and enlargement for flood control purposes. It is characterized by banks of varying steepness, turbid waters, and variable flows that respond to seasonal flooding and local rainfall events. In an unmodified bayou or stream, diverse aquatic habitats are created and maintained by bank caving, shoaling, log and debris jams, channel migration, and seasonal overbank flows. Many of those features, however, disappear with channelization and bank stabilization improvements. Most slow-flowing bayous also are characterized by dissolved oxygen depletions during the summer, where nutrient-rich waters experience high biological oxygen demand. Currently, the timing, extent, and frequency of average flows, stormwater discharges, and overbank flows along Bayou Pierre are undocumented.

Unmodified bayous and streams support fish spawning and nursery habitats in pools, slackwater areas, and flooded riparian zones. Slackwater outside of the main channel also contribute to overall stream productivity and diversity by providing major sources of plankton and macroinvertebrate production. The extent to which these habitats persist along Bayou Pierre is unknown, and fish populations are probably limited as a result of past habitat modifications

Terrestrial Habitats and Wildlife Resources

Land use in the study area consists primarily of woodlots, pine plantations, pastures, and rural residential areas. According to EPA's Watershed Information Network, land cover in the Bayou Pierre watershed consists of 25 to 50 percent forest riparian habitat, but notes that estimate is based on insufficient data (EPA 2000b). According to visual inspections at bridge crossings, Bayou Pierre is bordered by a narrow strip of riparian woodlands that varies in width throughout its length from 10 to 25 feet, to 50 to 100 feet. In some areas, particularly downstream of Wemple in De Soto Parish, no riparian zone remains at all and pasture or cleared fields extend to the shoreline.

Upstream of Wemple, much of the land outside the Bayou floodplain, particularly to the south and west, retains large forested areas of upland pine and pine-hardwood cover types (e.g., loblolly and shortleaf pines, and various oak and hickory species). Important forested wetlands are located in the Cannisnia Lake and Clear Lake-Smithport areas.

The Cannisnia Lake area, according to recommendations made by The Nature Conservancy to the Corps in 1994, is the most extensive example of mature hackberry-American elm-green ash-Nuttall oak bottomland hardwood forest community remaining in the Red River alluvial plain of northwest Louisiana. About half of the approximately 6,000-acre area qualifies as a significant natural area with old-growth characteristics, including baldcypress swamps in depressions and sloughs. Most of the Old Spanish Lake Lowlands area in the Little River watershed, between Powhatan and Allen in Natchitoches parish, are former bottomlands now cleared and converted to agriculture. The Old Spanish Lake Lowlands are a focus for acquisition efforts for the Red River NWR, and include several tracts enrolled in WRP and Partners projects.

Agricultural land use in the study area, especially downstream of Wemple, consists primarily of cotton, soybeans, and pasture. When flooded during the winter, crop fields generally provide valuable habitat for migratory waterfowl, especially if located adjacent to bottomland hardwood forests that provide nocturnal roosting cover. The extent and frequency to which such seasonal flooding occurs in the Bayou Pierre Basin is unknown.

The Red River, for example, rarely overflows its banks in northwest Louisiana, and the extent and duration of winter flooding in crop fields is minimal; most such flooding occurs in the area between the river and Louisiana Highway 1, where some fields are still planted in rice. Periods of prolonged and/or intense rain may provide waterfowl feeding areas in depressions and other areas of inadequate interior drainage in soybean, corn,

milo, and rice fields. Because those crops are minor components of agricultural land use in the study area, winter flooding along the Red River and Bayou Pierre is unlikely to provide much benefit to waterfowl. For this reason, most migrating ducks and geese rest only temporarily in northwest Louisiana before moving farther south to more suitable flooded rice and cornfields. Nonetheless, transient species of geese and dabbling ducks commonly observed in the study area include lesser snow goose, white-fronted goose, mallard, green-winged teal, blue-winged teal, pintail, gadwall, and American widgeon.

Other birds that frequent flooded fields and overflow areas adjacent to bayous and streams include wading birds (such as great egret, great blue heron, tricolored heron, green heron, and white ibis) and migrating shorebirds (greater yellowlegs, lesser yellowlegs, dowitchers, and sandpipers). Open-field birds that may be present in non-flooded areas can be found in Appendix B. A field checklist of the birds of the Bayou Pierre River Basin can be found in Appendix B as well.

Riparian habitat along Bayou Pierre has been significantly disturbed by agricultural development and stream modifications for improved drainage and flood control, and now supports a reduced diversity of plant and animal species. Riparian cover generally contains such bottomland species as American sycamore, American elm, hackberry, green ash, eastern cottonwood, black willow, sweet pecan, water-locust, and red mulberry; understory species may include roughleaf dogwood, red maple, and a variety of shrubs and vines. A list of plants commonly found in the study area can be found in Appendix B.

Riparian habitats are particularly valuable to wildlife as travel corridors and transition zones between aquatic and agricultural areas, and often provide the only forested habitat in rural areas characterized by large expanses of agricultural and pasture lands. Riparian woodlands also contribute vital elements to fishery resources in the form of detritus, shade, and in-stream cover. In addition to their wildlife habitat function, both riparian woodlands and forested wetlands floodwater storage areas, and maintain water quality by trapping suspended solids and assimilating dissolved nutrients and pollutants.

Forested wetlands of bottomland hardwood species border study area lakes, especially Cannisnia and Clear Lake-Smithport Lakes. Major species include water oak, Nuttall Oak, sugarberry, sycamore, red maple, green ash, bitterpecan, and sweetgum. In addition, wooded swamps within topographic depressions in those areas contain such species as baldcypress, tupelogum, water elm, and swamp privet. Like riparian woodlands, forested wetlands provide expanded fish spawning and nursery areas during flood season, as well as resting and feeding areas for waterfowl and other birds.

The Red River Basin in Louisiana, including the Bayou Pierre watershed, is located within a major mid-continental bird migration corridor. Many of the neotropical migratory landbirds seen along the Red River are trans-gulf migrants that need riparian woodlands both for stopover feeding and resting habitat during migration, and for nesting habitat during the spring and summer. Riparian woodlands generally provide important breeding and wintering habitat for a variety of migratory and resident birds such as

kinglets, wrens, kingfishers, woodpeckers, vireos, warblers, summer tanagers, and buntings. Raptors such as red-shouldered hawks, Mississippi kites, barred owls, screech owls, and great horned owls commonly nest and forage in these areas.

The value of avian habitat in riparian woodlands and forested wetlands of the Bayou Pierre study area, however, has been compromised due to forest clearing and stream modification. Resident wood ducks, for example, usually nest in riparian zones, using flooded woodlands and vegetated shallow water for brood-rearing habitat; such are scarce along Bayou Pierre. Likewise, undisturbed riparian woodlands are important for the survival of northwest Louisiana's restricted, restocked wild turkey population and for wintering American woodcock.

Mammalian species that may occur in reduced numbers in the study's area's remnant riparian woodlands include eastern cottontail and swamp rabbits, gray and fox squirrels, gray and red foxes, raccoon, opossum, nutria, beaver, mink, and white-tailed deer. The study area is home for numerous species of amphibians and reptiles. A list of these species is found in Appendix B.

Wildlife displacement during floods is not a critical problem in the Bayou Pierre Basin. Visual inspections by FWS of aerial photographs indicate that at least half of the basin's land area has been converted to agriculture, and does not provide high-quality wildlife habitat. Riparian wildlife are adapted to seasonal flood conditions. Individuals of certain species such as small burrowing mammals that are unable to climb trees or move to high ground may perish during floods, but such species also are able to replenish their populations fairly rapidly. The major problems in the Bayou Pierre study area is wildlife displacement due to forest conversion and fragmentation resulting from continued agricultural and urban development. That displacement may increase if new flood control measures contribute toward increased habitat loss.

Recreational benefits associated with fish and wildlife habitats would depend on the availability of access. Most of the land in the Bayou Pierre Basin is privately owned and not open to the general public for hunting, fishing, hiking, birding, or other recreational pursuits. In general, the public may access Bayou Pierre only at highway bridge crossings, and the navigability of Bayou Pierre throughout its length and throughout the year is unknown. One public boat ramp at Clear Lake-Smithport Lake apparently is a popular fishing spot even during the coldest days of winter.

Threatened and Endangered Species

Federally listed threatened or endangered species that may possibly occur in the study area include the threatened bald eagle (*Haliaeetus leucocephalus*), endangered interior least tern (*Sterna antillarum*), and endangered red-cockaded woodpecker (*Picoides borealis*). Nesting colonies of the interior least tern have recently been found on sparsely vegetated sandbars and islands along the Red River north of Natchitoches, but least terns are unlikely to be found more than a few miles from these sites except during migration.

Bald Eagles winter and infrequently nest near large lakes in central and northern Louisiana, and along the Red River in limited numbers, but there are no known nesting sites documented within the Bayou Pierre study area. Eagles may be observed in flight overhead or occasionally foraging over streams. Major threats to the bald eagle include habitat alteration, human disturbance at nest sites, and environmental contaminants (organochlorine pesticides and lead). Any new or undocumented nest site found in the study area should be protected; all Federal activities are generally prohibited within 1,500 feet of bald eagle nests, and certain other activities occurring within the 1,500-foot nesting zone are restricted to the non-nesting season. The Louisiana Department of Wildlife and Fisheries annually monitors and documents eagle nest sites. Eagles are also protected under the Bald Eagle Protection Act and the Migratory Bird Treaty Act.

A red-cockaded woodpecker (RCW) cluster was documented in 1984 within a half-mile of Bayou Pierre's west bank, near Wemple in De Soto Parish. The current status of this cluster, and of other potential undocumented clusters on privately owned lands, is unknown. The RCW is a nonmigratory, territorial species that requires open, park-like stands of mature (fifty years or older) pine stands with sparse hardwood midstories. RCW's excavate roost and nest cavities in living pine trees; the area encompassed by a family group's cavity trees, with the surrounding mature pine foraging habitat, is known as a cluster. Much logging has occurred in the local area since 1984, and the little mature pine forest that remains does not provide good RCW habitat because of excessive hardwood encroachment. Any Federally funded work proposed in the study area at sites containing suitable habitat should be surveyed by a qualified biologist for the presence of RCW clusters. The survey should include a quarter-mile buffer zone around the entire right-of-way proposed for each alternative plan. A copy of the site inspection report should be provided to the FWS office and should include the following: (1) stand characteristics, including pine basal area, number of pines at least 10 inches DBH or older than fifty years, and species of dominant vegetation within each canopy layer; (2) number of active and inactive RCW cavity trees observed; (3) presence or absence of RCWs; and (4) topographic quadrangle maps delineating areas of adequate RCW habitat, cluster sites, and cavity tree locations relative to proposed construction activities. If an active cluster or suitable RCW habitat is present in an area to be cleared, further consultation with the FWS is necessary.

Christmas Bird Count

The primary objective of the Christmas Bird Count is to monitor the status and distribution of bird populations across the Western Hemisphere. The count period is from December 14th to January 5th, in North America is referred to as “early winter.” Because many birds at this time are still in the late stages of their southward migration, so it is not “true” winter.

More than 50,000 observers from the Western Hemisphere (predominately the United States) participate each year in this census of early-winter bird populations. The results of their efforts are compiled into the longest running database in ornithology, representing over a century of unbroken data on trends of early-winter bird populations across the Americas.

Within the study area there are three Christmas Bird Counts (C.B.C.). All of the counts are conducted in a fifteen-mile diameter circle from a center point. The Caddo-Bienville Christmas Bird Count has been conducted annually since 1988. The Caddo-Bienville count is conducted in a fifteen-mile diameter circle centered 2.5 miles southeast of McDade. This area encompasses portions of Bossier, Caddo, Bienville, and Red River parishes with the center located approximately Latitude 32° 18’N, Longitude 93°29’W.

The Natchitoches Christmas Bird Count has been conducted annually since 1965. The Natchitoches count has as its center the intersection of highway 71 and Route 6 at Clarence, Louisiana which has a Latitude of 31° 49’N and Longitude of 93°03’W, and is a 7.5 mile radius. By far the most prominent C.B.C. is the Shreveport C.B.C. which has been going on since 1950. The center of the Shreveport C.B.C. is within 3 miles of Blanchard, Louisiana, which is located at Latitude 32°32’N 93°53’W. For a listing of the species detected in the annual counts see Appendix B.

Recreation

The study area is adjacent to areas that provide recreational opportunities to the public. These include the Bayou Pierre Wildlife Management Area, which is a 1,337-acre refuge area located in Red River Parish. A map of the management area can be found in Appendix B. More discussion on the management area can be found in the previous Special Emphasis section in this document. The Red River to the east and with the recent system of locks and dams in place, has potential for utilization for water sports and fishing. A series of public boat ramps and recreation areas are planned at numerous points along the Red River.

In addition to the recreational opportunities discussed above, needs for future recreation have been identified. The State of Louisiana prepared the 1993 Statewide Comprehensive Outdoor Recreation Plan (SCORP) which describes significant recreation issues, strategies, and recommendations. During plan preparation, an analysis of recreation demand, supply, and need was conducted. Information was gathered through workshops held across the state; a survey of outdoor recreation use organizations,

communities and parishes; a Lieutenant Governor's Task Force on Outdoor Recreation Resources; and an inventory of federal, state, local, and private recreation programs that together constituted the development of this plan (Louisiana Department of Commerce, Recreation, and Tourism, 1994)

National Wildlife Refuge

The nation's newest wildlife refuge in the project area was recently dedicated in August 2002 with 600 acres being established to trees. The area is the first national wildlife refuge along the Red River Valley, which consists of about 800,000 acres from the Arkansas border to Alexandria. A map of the wildlife area is shown in Appendix D. The Red River NWR Act was recently passed by Congress and has received presidential approval. The authorizing legislation recognizes the Red River Basin in Louisiana, which encompasses the Bayou Pierre Watershed, as an internationally significant resource owing to its location within a major bird migration corridor.

The Bayou Pierre study area essentially coincide with the refuge's proposed Bayou Pierre Floodplain selection area, which is designated from north of the city of Natchitoches to Louisiana Highway 175 southeast of Wallace Lake. That selection includes Clear Lake-Smithport Lake, Cannisnia Lake, Bayou Pierre Lake, and their associated forested wetlands. The selection area also encompasses the Little River Basin, which contains the area known as the Old Spanish Lake Lowlands in Natchitoches Parish. Acquisition of the proposed refuge is strongly supported by the local community in Shreveport, primarily through the efforts of the non-profit Friends of the Red River NWR.

This historic region has been used for migratory birds funneling through the mid-continent from as far north as the Arctic Circle and as far south as South America. Up to 50,000 acres stretching across northwest Louisiana in Caddo, Bossier, Red River, Natchitoches and De Soto parishes may be incorporated into the refuge. The refuge, located in an area known as the Old Spanish Lake Lowlands, is the product of a carbon trapping project that will offset the environmental impacts of fossil fuel emissions, provide new fish and wildlife habitat and bring recreation-driven economic benefits to the northwest Louisiana along the Red River Valley in Natchitoches Parish.

The refuge is to provide for the restoration and conservation of fish and wildlife habitats in the Red River Valley ecosystem in northwest Louisiana. However, since the 1820s, the Red River Valley has been almost totally cleared of its forest cover, primarily due to agricultural production.

The tree shrub planting on the refuge will aid in reducing 275,000 tons of carbon in the next 70 years. Plants remove CO₂ from the air and convert it into sugars that are used to produce substances needed to sustain their growth and development. Many of these CO₂-derived products, particularly lignin and cellulose, are present in large quantities within the woody tissues of trees and shrubs. Hence, as long as these plants are alive and growing, they actively remove carbon from the air around them (Chambers *et al.*, 1998).

ECONOMIC RESOURCES

Population

Table 1 contain summaries for the 1980, 1990 and 2000 Census Bureau population counts for the five parishes in the study area, as well as the state of Louisiana and the United States. Population trends in the basin reflect employment, natural resources development, and changes in technology and transportation.

Table 1. Total Population of Parishes within the Bayou Pierre River Basin.

Population	1980	1990	2000	% Change 80 - '90	% Change 90 - '00
Caddo	252,437	248,253	252,161	-1.7	1.6
De Soto	25,727	25,699	25,494	-0.1	-0.1
Natchitoches	39,863	37,199	39,080	-6.7	5.1
Red River	10,433	9,518	9,622	-8.8	1.1
Sabine	25,280	22,646	23,459	-10.4	3.6
Louisiana	4,206,116	4,221,826	4,468,976	0.4	5.8
United States	226,542,204	248,765,170	281,421,906	9.8	13.1

As illustrated in Table 1, the population in each of the parishes within the basin grow less rapidly than the state and national averages for all periods. The most dramatic decrease was between 1980 and 1990, which reflects the outflow of people during a period of high unemployment.

Education Attainment

Table 2, illustrates an increase in education rates of people of 25 and older for 1990 and 2000. Each parish shows an increase between the two time periods for high school graduation rates. Most all parishes increased the rate of people of 25 and older with Bachelor's degrees or better from college between the two time periods. However, each parish and the State of Louisiana are below the national average for both categories during the time period.

Table 2. Education Attainment (%)

Education	1990		2000	
	High School	College	High School	College
Caddo	73.4	18.2	78.7	20.6
De Soto	64	9.5	70.3	10.2
Natchitoches	65	16.4	72.7	18.4
Red River	57.4	8.7	67.4	8.7
Sabine	61.9	8.3	70.8	11.1
Louisiana	68.3	16.1	74.8	18.7
United States	75.2	20.3	80.4	24.4

Income

Table 3, illustrates that per capita income has increased between 1990 and 2000. However, during both time periods all parishes except Caddo parish were below the state average. During both time periods the state and parishes were below the national average.

Table 3. Per Capita Income.

<u>Income</u>	<u>1990</u>	<u>2000</u>
Caddo	11,604	17,839
De Soto	8,330	13,606
Natchitoches	8,112	13,743
Red River	7,213	12,119
Sabine	8,539	15,199
Louisiana	10,635	16,912
United States	14,420	21,587

The percentage of the population below the poverty level (Table 4) follows the per capita income data. The state and parishes in the data series are all above the national average for population percentage below the poverty level. All parishes have higher rates of poverty than the state average.

Table 4. Percent of People Below the Poverty Level.

	<u>1989</u>	<u>2000</u>
Caddo	24.0	21.1
De Soto	29.8	25.1
Natchitoches	33.9	26.5
Red River	35.1	29.9
Sabine	27.1	21.5
Louisiana	23.6	19.6
United States	13.1	12.4

Employment

Total employment, the five-parish area, increased from 1990 to 2000, reflecting improving economic conditions (Table 5). Red River is the only parish that had an increase in unemployment rate between 1990 and 2000. However, all parishes that are part of the study had a higher unemployment rate than the state and national averages.

Table 5. Civilian Labor Force (CLF) and Unemployment (UE).

Employment	1990		2000	
	CLF	UE	CLF	UE
Caddo	111,342	11.2	115,370	9.3

Table 6 contains the industrial sector income for the parishes in the study area. The most income is in the manufacturing, services, and governmental enterprises sector. The agricultural sector is the smallest sector for income generated in each of the parishes. The income information is from the Bureau of Economic Analysis data for 1998.

Table 6. Industrial Sector Income by Parish within the Study Area.

Tourism

The office of State Parks lists the following facilities in the study area: The Mansfield State Historic Site, which is a civil war battle, site. The state operates this 178-acre site with a museum, picnic area and trails. Rebel State Historic Site is the site of a grave of an unknown rebel soldier. The 46-acre site has a museum, picnic area and trails.

Los Adaes State Historic Site is a 1730's Spanish fortification site. This 57-acre site has an archaeological workshop, interpretive exhibits and trails. The State of Louisiana plans

to build a “first class” interpretive center at Los Adaes, the site of the former Spanish colonial capital of Texas, near Robeline. The Louisiana Department of Culture, Recreation and Tourism has \$250,000 to help develop plans for the site. The site is unique, and the project when completed will be a full reconstruction of the Spanish mission, a partial reconstruction of the presidio and full reconstruction of several housing sites to display daily life in the Spanish colonial period. Los Adaes is located about one mile east of Robeline off Louisiana Highway 6.

The Parish of Caddo Parks and Recreation Department maintains four parks and recreation areas within the project area. Milton “Hookie” Cameron Memorial Park is a one-acre park at the end of Wallace Lake Road on Wallace Lake. The park consists of a circular drive, parking and a boat ramp. The park is primarily used by fishermen and duck hunters to access the lake. The department also maintains a boat ramp at the end of Norris Ferry Road on Wallace Lake.

Hannah’s Park has been developed within the last year in the Mount Pleasant Acres Subdivision. This 1 ½ acre park located on Oak Grove Lane provides a covered picnic area, playground equipment and open space for the neighborhood.

The largest park and recreation area in the Caddo Parish portion of the study area is the Eddie Jones Park Development located along LA 789 east of LA 169. This project began in 1999 on 1200+ acres owned by the Parish of Caddo, adjacent to the Fort Wade Correctional Center. Approximately 81 acres of this property is in the process of being transferred to the State of Louisiana so that the Department of Veteran Affairs can develop a Veterans Cemetery on the site. Two hundred acres has been donated to a non-profit organization known as Chimp Haven, Inc., to develop a chimpanzee sanctuary. The remaining property will be developed as a nature park with multiple use trails for hiking, nature study, mountain biking and horseback riding. This development is expected to become an important recreation area and tourist attraction for the Parish (Parish of Caddo Parks and Recreation).

Oil and Gas Wells

Louisiana ranks among the top four states in oil and gas production, and is second in per capita energy consumption. It has produced oil and gas for almost a century. In 1870, a night watchman at an ice plant in Shreveport accidentally discovered natural gas emanating from a well drilled in search of artesian water when he struck a match. Gas from the well was piped to the plant to provide illumination, the first use in the state of the fuel that today heats the vast majority of Louisiana homes and places of business. In 1908 the first natural gas pipeline was laid in Louisiana. It brought gas from the Caddo Field to Shreveport. In 1909 construction began on Louisiana's first long-distance oil pipeline, which by 1910 was transporting oil from Caddo Parish to the Baton Rouge refinery which today is known as Exxon. Table 7 shows the oil and gas activity profile of the parishes in the study area. Location of oil and gas wells in the study area can be found in Appendix D depicts the oil and gas locations in the study area.

Table 7. Parish Oil and Gas Activity Profile 2000

Parish	Royalty	Oil Severance	Gas Severance	Total Wells	Employees
Caddo	\$745,315.04	\$3,160,169	\$1,195,732	240,516	3,682
De Soto	\$473,449.64	\$ 747,181	\$3,052,913	13,630	141
Natchitoches	\$ 33,415.48	\$ 219,973	\$ 266,527	1,896	176
Red River	\$ 56,761.14	\$ 50,664	\$ 90,902	2,033	27
Sabine	\$ 68.19	\$ 110,601	\$ 141,336	6,078	77

Coal Mining Operations

Coal is a relatively new source of energy in Louisiana. Large amounts of coal from other states were first consumed in Louisiana in the early 1980's to generate electricity. Production and consumption of Louisiana's coal, all lignite, began in the mid-1980. Although the annual output of lignite has risen to about 3 million short tons, its role in Louisiana's economy is greatly overshadowed by the large amounts of natural gas and crude oil produced in Louisiana.

Lignite was found in the northwestern part of Louisiana as early as 1812, nearly a century before petroleum was discovered in Louisiana. Around the turn of the century, lignite was used to heat a school near Mansfield. In the 1950's and 1960's, lignite was recognized as a potential fuel for generating electricity in the State, and large reserves were delineated in the Dolet Hills area, near Mansfield which is in De Soto Parish. At the time, however, lignite was not cost-competitive. The economics changed in the late 1970's as pricing and legislation limited the use of natural gas as a power plant fuel.

In 1985, the Dolet Hills mine, operated by Dolet Hills Mining Company, began supplying lignite to the power plant's stockpile by use of a 7.5-mile-long conveyor. The following year, the power plant began commercial operations with a generating capability of 650 megawatts. In the late 1989, a second, smaller surface mine, the Red River Mining Company's Oxbow Mine at Coushatta, Louisiana was opened to provide an additional source of lignite, delivered by truck to the power plant. Dolet Hills Lignite Company is a wholly owned subsidiary of Southwestern Electric Power Company (SWEPCO),

employing some 150 people. Dolet Hills surface mine produces approximately 3 million tons of lignite per year for the nearby Dolet Hills Power Station, which is co-owned by SWEPCO and CLECO Power LLC. An inventory, in millions of tons, of the lignite production from Dolet Hills and the Oxbow mines during the years of 1985 – 1992 is shown in Table 8.

Table 8. Louisiana Lignite Production in Millions of tons for 1985-1992.

Year	Mine		Total (Million Tons)
	Dolet Hills	Oxbow	
1985	392,815	0	392,815
1986	2,067,867	0	2,067,867
1987	2,750,652	0	2,750,652
1988	2,889,489	0	2,889,489
1989	2,879,806	102,753	2,982,559
1990	2,746,096	440,093	3,186,189
1991	2,740,733	410,015	3,150,748
1992	2,653,455	553,950	3,207,405

Reclamation Success

The Red River Coal Mining Company was nominated for the Interstate Mining Compact Commission's Reclamation Award in 1999. The Company was especially recognized for its innovative management of groundwater in the mining of a large flood plain area. The Oxbow Lignite Surface Mine, located near Coushatta, Louisiana, supplies approximately 750,000 tons of lignite per year. The mine is a single – seam, dragline, surface operation. The project was unique in several aspects. It was the first time the slurry wall technology was used for such a large flood plain area to manage groundwater.

A dewatering system was installed to remove the existing ground water in the mining area after the slurry wall was in place. Discharged water traversed a mile long stretch of grassy ditch to a sedimentation pond, and was finally released into Bayou Pierre. Discharges were studied and monitored to make certain they met water quality standards.

After the mining activities are completed, the slurry wall will be cut in several places to allow for the re-establishment of ground water flow. The sedimentation pond will be a permanent feature to the reclaimed area. It serves to enhance the appearance of the site and benefit the wildlife (Mineral Information Institute 2002).

PROBLEM IDENTIFICATION

This section of the report will provide background information on the why, what, and how aspects of the study. The discussion will center around why the study was initiated, what the resource problems are, and how the problems impact the area. Discussion will center on the information provided by the sponsors, and members of the Technical Steering Committee. In addition, there were five public scoping meetings held: in 1) Keithville on January 18, 2000; 2) Coushatta February 1, 2000; 3) Stonewall February 8, 2000; 4) Pleasant Hill February 15, 2000; and 5) Natchitoches, LA February 24, 2000. The purposes of these meetings were to solicit public input for the Bayou Pierre Cooperative River Basin Study.

From the five public meetings, 103 Problems/Issues/Concerns were recorded. The TSC reviewed the problems/issues/concerns. Due to the similarity of the problems/issues/concerns from the citizens, they were grouped into broad-based categories shown below. Comments are group as a percentage of the total comments that were received. The dominant problems/issues/concerns are addressed in this section

Problem/Issue/Concern	Percentage of Total Comments
Flooding	60
Planning	14
Water Quality	8
Recreation	7
Watershed Protection	4
Education	2
Irrigation	1
Tourism	1
Previous Watershed	1
Water Supply	1
Economics	1
Wetlands	1
Groundwater Recharge	1

Resource problems/issues/concerns in the study area have been a concern of the constituents of the river basin area for some time. A list of prior studies, report, and existing water projects can be found in Appendix E.

Principal Flood Problems/Drainage Patterns

The Bayou Pierre Cooperative River Basin Study lies within the alluvial plain of the Red River. Before man's intervention, floodwaters regularly flowed over the banks of the Red River into this valley. Floodwater and excess rainfall within the basin were drained

by a network of streams running parallel to the Red River. These streams and the overall alluvial valley were quite flat and contained many large areas of natural depression. The runoff was quite slow and the land remained inundated for long periods.

The most important deterrent was the construction of a levee system along the Red River. Since its expansion in 1946 this levee has not been breached. A current major flooding source is a large watershed external to, but discharging through, the 1,108.6 square mile Bayou Pierre River Basin study area.

Repetitive Flood Losses

A Repetitive Loss property is a property that is insured under the National Flood Insurance Program and has filed two or more claims in excess of \$1,000.00 each, within a 10-year period. There are about 40,000 buildings across the country currently insured under the National Flood Insurance Program (NFIP) that have been flooded on more than one occasion and that have received flood insurance claims payments of \$1000 or more for each loss. The cost of these multiple loss properties over the years to the NFIP has been astonishing - - \$1.8 billion (NFIP 2003). A listing by zip code of the properties that have benefited by FEMA's program in the river basin is shown in Table 9.

Table 9. Federal Emergency Management Agency Repetitive Loss Data up to June 30, 2000

Zip Code	Loss Count	Total Payments
71019	5	\$ 42,099
71032	1	\$ 488
71052	4	\$ 94,505
71105	57	\$ 462,361
71106	71	\$ 780,620
71108	32	\$ 151,445
71115	14	\$ 64,426
71118	65	\$ 862,501
Total	249	\$ 2,458,445

According to FEMA in order to get secured financing to buy, build, or improve structures in Special Flood Hazard Areas (SFHA) you will be required to purchase flood insurance. Lending institutions that are federally regulated or federally insured must determine if the structure is located in a SFHA and must provide written notice requiring flood insurance. There's a big difference between having to buy flood insurance because the law says you must and choosing to buy flood coverage because it's in your best interest to do so. In fact, about 25% of all flood claims occur in so-called moderate or minimal flood risk zones.

According to FEMA, flooding is the leading cause of property loss from natural disasters in the United States. In 1968, Congress created the National Flood Insurance Program. This Federal program provides flood insurance at a reasonable cost in exchange for the careful management of flood-prone areas by local communities. There is a 26 percent chance of experiencing a flood during the life of a 30-year mortgage compared to a 4 percent chance of Fire.

Caddo Parish Portion of the Study

The City of Shreveport is the center of commerce for northwest Louisiana, and has an extensive diversified industrial economy with 380 plants producing more than 700 different products.

The growth patterns in the City of Shreveport are typical of a large urban community with private residences, apartments, and shopping centers expanding away from the central business district. The principal direction of movement has been to the south. Northward movements have been limited by the geographical barriers of Cross Lake, the Red River, and their floodplains. In the last few years, however the availability of land above the floodplains has dwindled and construction has begun to infringe on low lands.

A major concern to the constituents in the northern extremities of the study area is the flooding problems associated with Wallace Lake. According to the Corps of Engineers, the Wallace Lake flood control dam was completed in 1946. Wallace Lake is a “dry dam” flood control lake constructed on Cypress Bayou. The Cypress Basin reaches north to Interstate 20 and westward into Texas. The fee-purchased land was limited to the damsite area (approximately 280 acres) and on each side of the Kansas City Southern Railway rights-of-way crossing the reservoir, with the rest of the reservoir area in privately owned land over which the Government was granted perpetual flowage easements. These easements, in general, forbid construction below an elevation of 158 feet, National Geodetic Vertical Datum (NGVD), but structures may be built between 158 and 165 feet, NGVD, at the risk of the owner, according to the Corps. The project provides substantial protection to approximately 90,000 acres of agricultural lands below the dam.

The Corps of Engineers has the right of water level control up to an elevation of 165 feet. The spillway and outlet works of Wallace Lake are a combined structure, that is automatic in operation, consisting of an uncontrolled, overfall concrete spillway and an uncontrolled outlet structure. The spillway is 644 feet in width and is located in the dam near the south abutment. The outlet works are located in the center of the spillway and consists of an entrance section, four rectangular conduits, 3 x 8.25 feet, and a separate stilling basin. The discharge capacity of the spillway with the surcharge pool at maximum elevation 170.7 feet is 112,700 cubic feet per second including conduit discharge. The discharge capacity of the conduits with the pool at elevation 158.9, spillway crest, is 2,600 cubic feet per second (USACE 1975).

The Coalition of Wallace Lake of Flood Victims have identified the following problems associated with the Wallace Lake Reservoir:

- **Flooding of Homes**
- **Closing of Highways**
 - Disruption of traffic flow on I-49
 - Linwood Avenue (Major thoroughfare) closed for two weeks
 - Secondary roads closed for several days
 - Soil base problems (I-49 sinking in spots)
- **Economy**
 - City of Shreveport/Caddo Parish growth and revenues
- **Extreme Fluctuation in Lake Levels**
 - Lake levels fluctuates from 2,000 to 10,000 acres in 2-3 days.
- **Environmental Results**
 - The Bayou Pierre watershed in its natural state was a major tributary to help drain northwest Louisiana. The main factors that have impacted the natural drainage are:
 - The levee system along the Red River which prohibited water from the west flowing directly into the river thus causing this water to flow along bayous parallel to the river and ultimately into the river downstream.
 - Development of metropolitan Shreveport, thus eliminating forests and fields that were the natural and absorbed runoff. This conversion to hard surface speeds up the flow of more runoff.
 - This runoff traditionally was dispersed and absorbed but it is concentrated and accelerated into the natural tributaries that do not have the carrying capacity to handle this increased volume.

The Red River, which forms the easterly boundary of the City of Shreveport, is one of the principal rivers in the State of Louisiana. Its mouth is formed at the Old River control structure that regulates the diversion of low water from the Mississippi River. The City of Shreveport sits at mile 277 of the Red River, which has a drainage area of 60,614 square miles at that point. The city is protected from possible flooding of the river by the natural high ground of the central business district and a system of artificial levees for the remaining portions of its length. Very little direct runoff from the City of Shreveport flows into the Red River.

All runoff from the City of Shreveport does eventually reach the Red River. Runoff from the northern portion of the City flows into the Cross-Bayou Basin, which intersects the Red River, just north of the central business district. The majority of the area runoff flows into the Boggy Bayou or Brush Bayou basins, which flow into Wallace Lake and then connect, to Bayou Pierre.

The Boggy Bayou Basin drains the southwestern section of the City of Shreveport. The area is largely undeveloped. The topography of the area varies from 160 feet NGVD along Boggy Bayou to 320 feet NGVD at the headwaters of Industrial Park Lateral. Relatively flat topography extends from the downstream reaches of Boggy Bayou, Gilmer Bayou, and Industrial Park Lateral.

Bayou Pierre parallels the Red River from the City of Shreveport to Natchitoches (70 miles) before their confluence. The Bayou Pierre drainage area drains the southeastern portion of the City of Shreveport and this basin is quite unique. The northern portion of the basin and the portion west of Bayou Pierre are heavily urbanized as the land is relatively high. In the area west of Bayou Pierre and south of Southfield Road, the development is relatively sparse, having an estimated 20% urbanization. The land here is quite flat ranging from elevation 140 feet NGVD to 165 feet NGVD.

The Federal Emergency Management Agency, developed several reports regarding flooding problems in Shreveport. Some excerpts from these report are as follows:

“Primary flood problems in the metropolitan area exist in the Brush Bayou Basin, along portions of the upper reach of Bayou Pierre, and in the alluvial bottom lands that remain exposed to inundation from Red River and Twelve Mile Bayou. (Federal Emergency Management Agency Flood Insurance Study 1995)

“Flooding along Bayou Pierre is, in general, confined to that portion of the basin below the hill line and within the limits of the Red River Alluvial Valley. Floods in Shreveport have been increasingly important during the last 20 years because of its rapid development. The greatest flood of record, that of 1933, overflowed 5,500 acres of bottomland above mile 70, of which 500 acres were in a select residential section of the city. Highest recorded stages for this flood in Bayou Pierre were 165.8 feet Mean Sea Level (MSL) at Ockley Drive Bridge, 167.0 feet in Ockley Drive Ditch, and 171.0 feet at the levee crossing. (Federal Emergency Management Agency Flood Insurance Study 1995)

Natchitoches Parish Portion of the Study

The existing levee system along the Red River consists of a levee running southeast along the west bank from the parish corporate limits above the Village of Powhatan to the confluence of Bayou Pierre, above the City of Natchitoches. The levee resumes below Bayou Pierre and runs in a southern direction across the Cane River to the hills on the south bank in the southeast corner of the parish.

The area north of the City of Natchitoches is subject to backwater flooding of the Red River through bayou Pierre and its tributaries. On April 10, 1945, the Red River reached a stage of 119.79 feet at Grand Ecore approximately 3 miles north of the City of Natchitoches. Although the existing Red River Levee system saved portions of the City of Natchitoches, most the Cane River Basin was flooded.

Inadequate Floodplain Management Due To Rapid Development

The rapid development around and adjacent to south Shreveport has and will continue to impact drainage in both the urban and rural areas within the study area. Development and Floodplain Management around the Wallace Lake area was discussed as a problem during the study duration. As the floodplain is filled with earth, streets, buildings, etc. the volume of storage available for floodwater is depleted. The soil's ability to allow water to infiltrate or percolate into the ground is virtually eliminated when the ground is covered by concrete or other impervious materials. Practically all of the rain that falls on the impervious surface becomes runoff that must be conveyed by the drainage system. These two factors can and have increased flooding within the developing areas.

With the change in land use to urbanization also comes an increase in water pollution. Because most home and business lawns are intensively managed to be aesthetically pleasing to the eye; fertilizer, pesticide, and herbicide use is significantly higher than when the land was used for agricultural or forest usage. These fertilizers and chemicals are flushed into the receiving water bodies in rather large concentrations.

As development occurs it also impacts existing developed areas. What was once an adequate drainage system can become overtaxed by the additional water and causes flooding in the older developed area that had drainage prior to the adjacent land use changes.

While rapid development presents flooding and water quality problems, one of the hardest tasks is enforcing fair and equitable floodplain and zoning ordinances. Minimum requirements have been established by the Federal Emergency Management Administration for developing in floodplains. Zoning is regulated by local governments and commissions. Development creates a tax base that is necessary for any community to survive. There in lies another problem. Zoning and floodplain ordinances are very political issues and must be handled in such a manner that adequate regulations are in place that does not inhibit the growth of the community.

Water Quality

Water quality problems within the study area are primarily from nonpoint sources (NPS) in lieu of point sources. NPS pollution is caused by diffuse sources that are not regulated as point sources and normally are associated with agricultural, silviculture and urban runoff, runoff from construction activities, etc. Nonpoint source pollution does not come from a single source location (such as a single pipe from a factory or waste treatment plant) but generally results from land runoff, precipitation, atmospheric deposition, or percolation (LDEQ 1993). Water quality impairment causes monetary, health, and aesthetic problems within the study area. In addition, fishery and wildlife use is limited, as are the recreational opportunities associated with these resources.

Dissolved Oxygen (DO)

Low dissolved oxygen level has been identified as a problem in the study area. As organic materials decompose, they consume oxygen. Excessive quantities of organic materials result in oxygen depletion in the receiving stream due to this decomposition process. As oxygen levels are depleted, the ecosystem of the stream can become unbalanced and the result can be fish kills and nuisance conditions. A few examples of oxygen-demanding substances include animal droppings, sewage overflows, leaves, agricultural crop debris, and grass clippings. As such, the lower DO levels at certain times of the year, especially in summer and low flow periods, have resulted in limited propagation of fishery resources in the effected bayous or channels within the study area.

Sediments

Sediment loading within the monitored water bodies in the river basin is proportional to soil erosion and the type of soil eroded. The soils within the study area are very fine-grained silts and clays with some sands. These fined grained materials are easily eroded and the clay particles will stay in suspension under very low energy environments. Sediments can smother benthic organisms, interfere with photosynthesis by reducing light penetration (turbidity), and fill in waterways which increases flooding. In addition, nutrients, pesticides, and other organic compounds can attach to the sediment particles and be flushed into the water body (LDEQ Nonpoint Source Assessment Report 1993). As discussed earlier, the sediments that settle within the waterways pose significant maintenance costs and the pesticides and other nutrients present a threat to human, fisheries, and animal health.

Nutrients

Water quality problems associated with nutrient loading are most noticeable in the fall. It is during these low flow periods of late summer and fall that alga blooms and associated fish kills are more numerous. In general, the runoff from lands used for agricultural uses has a significantly higher nutrient concentration than forestlands. The same is true for the runoff from urban areas. The principal nutrients are washed from fertilized fields and lawns into the receiving stream. In addition, these nutrients can be attached to soil particles that have been eroded and suspended in the runoff. While nutrients are essential to plant growth in a water body, excess causes alga blooms that in turn impacts fisheries production. As with the other forms of pollution, nutrient pollution causes financial and health problems within the study area.

Watershed Protection

Watershed protection is the onsite treatment of watershed areas for the primary purpose of reducing offsite soil and water related resource problems associated with floodwater, erosion, sediment, and agriculture related pollutants.

Louisiana Department of Environmental Quality Nonpoint Source Management Plan has indicated that Wallace Lake was not meeting the designated uses for either contact recreation (primary and secondary) or fish and wildlife propagation. The suspected causes for this lack of use support included organic enrichment/low dissolved oxygen, pathogen indicators, metals, lead and mercury. As a result of the findings the Environmental Protection Agency (EPA) Region 6 approved this project for funding through the FY 2000 Section 319 grant. (Nonpoint News 2001). Three sites have been selected for monitoring. The agricultural site is a dairy, there is a forestry site and the urban site consists of a subdivision that is partially developed and partially undeveloped. Monitoring of these sites will commence May 2003 and will continue for 3 years.

The development of the watershed plan is based on land-use and nonpoint source pollutant loading data from three demonstration areas within the watershed. In-stream water quality, hydrology and biological data will also be collected to establish a baseline indication of aquatic health from which to measure and track improvement as the watershed plan is implemented. (LDEQ Nonpoint News 2001)

Wallace Lake is scheduled for development of a total maximum daily load (TMDL) by December 2005; therefore the data collected will also help with the nonpoint source portion of that calculation. (Nonpoint News 2001)

Best management practices will be implemented at forestry, urban and agricultural demonstration sites in order to quantify the nonpoint source pollutant-loading rate that occurs. There have been forested areas within the watershed of Wallace Lake and other locations within the study area where timber was harvested and tops and debris were left after harvest.

The aforementioned demo sites will also be utilized for education and outreach to local landowners within the watershed as a method to inform them of their cost effectiveness and their water quality benefits. (Nonpoint News 2001)

Groundwater Management

Louisiana has historically been regarded as a water-rich state. Water rights have provoked minimal litigation in Louisiana, however the state's legislators have attempted coordinating the development and protection of water resources and regulating the use of water. Groundwater resources in the study area must be managed carefully in order to avoid water-level declines, declining well yields, and local water quality deterioration. A national survey in 1978 listed Louisiana as one of only eight states where over half or close to half of the state's land mass is subject to groundwater depletion – the others being Nebraska, Kansas, Oklahoma, Texas, Colorado, New Mexico, and Arizona. In

fact, of all of these states, Louisiana appeared to have the largest percentage of its surface area affected by depletion. Groundwater resources could be threatened by the unrestrained uses of the resource.

Irrigation

According to the Water Use in Louisiana, 2000 Report, over 8 million gallons of water per day is pumped for rice from the Carrizo-Wilcox, the Red River Alluvial and the Sparta Aquifers in the study area. A concern on the part of the farmers in the area is that the water is not evenly distributed. The Bayou Pierre River Basin area partially overlays the Red River Alluvial Aquifer, which is very shallow and contains water with an extremely high iron content. Many producers have installed wells only to find that water could not be pumped in sufficient quantities to meet their needs. In order to decrease the demand placed on the limited amount of water in the Red River Alluvial Aquifer water from the Red River could be utilized.

Recreation

There is concern by the residents in the project area with Clear Lake, which is a natural Lake, and Smithport Lake, a manmade lake. Together these lakes have 2959 acres of surface water at 131.6' mean sea level (Powell Appraisal Service 2002). The amount of fishing has decreased in recent years due to the amount of aquatic vegetation. Aquatic plant life is desirable in aquatic habitats. However, when aquatic plants begin to flourish and negatively affect human activities, these plants are referred to as "weeds." The "weed" determination may be based on the location in which the plants are growing such as boating lanes or around boat docks. Problems also arise when the aquatic plants interfere with the intended use of the body of water such as swimming, skiing or fishing. The aquatic vegetation that is causing problems includes duckweed, hydrilla, and lilly pads.

A lack of public boat ramps in the study area has hampered water sports and fishing to some extent. As mentioned previously. The one public boat ramp at Clear Lake-Smithport Lake is a popular fishing spot.

There is also some public concern for the recreation around Fort Jesup (hiking trail, Los Adaes, Rebel State Park, Caddo Dai Tribe). These areas including the roads in the vicinity of Fort Jesup need improving. There is a combination of dirt and blacktop roads that recreation enthusiasts have to utilize.

Aquatic Health of Study Area

The U.S. Environmental Protection Agency (EPA) has determined an overall index of aquatic health in the Bayou Pierre watershed, based on indicators of current conditions and future vulnerability of aquatic resources (EPA 2000a). The score for Bayou Pierre indicates "more serious water quality problems" but "low vulnerability to stressors such as pollutant loadings, " and that aquatic conditions in general are "well below state water

quality goals” (EPA 2000a). Available EPA data suggest that pollutants or other aquatic stressors are a low-priority problem, indicating a relatively low potential for future declines in aquatic health and a low vulnerability index for aquatic species at risk. EPA’s interpretation of the overall watershed score for Bayou Pierre notes that actions to prevent declines in aquatic conditions are appropriate, but at a lower priority than in more vulnerable watersheds.

Serious problems exist, however, regarding Bayou Pierre’s designated use attainment and ambient water quality, especially in regard to dissolved oxygen, ammonia, phosphorus, and pH. Agricultural runoff also registers a high vulnerability indicator due to nitrogen, sediments, and pesticides. EPA notes that the Bayou Pierre watershed index is based on insufficient data, especially regarding land-use cover, fish and wildlife consumption advisories, and source water condition (EPA 200a and 2000b)

Fish and Wildlife

The major fish and wildlife resource issues disclosed by this preliminary review concern both aquatic and terrestrial habitats along Bayou Pierre. Reduced aquatic habitat diversity, including that associated with both main channel and slackwater areas, and associated changes in fish populations, could result from additional modifications for channelization, bank stabilization, and flood damage reduction. Altered aquatic habitats support a lower diversity and reduced abundance of fish species. Many of those species are tolerant of the low dissolved oxygen conditions that commonly occur in warm, low-flow conditions; many also are of potential recreational importance.

Terrestrial habitat losses would occur with the destruction of riparian woodlands at construction sites, along flooded shorelines upstream of dams or weirs, and with increased agricultural and residential development in response to improved flood control. Moreover, habitat losses resulting from all these impacts would be cumulatively related to losses from prior stream modifications.

Education

There are many stakeholders in a river basin. However many of the stakeholders are not aware of the need for such items as watershed protection, non-point source pollution, control restrictions on developing in a floodzone, best management practices, various conservation practices, sources of technical and financial assistance.

ALTERNATIVE SOLUTIONS TO PROBLEMS

Alternative solutions or recommendations were discussed at the various public meetings. Each of the alternate solutions will be discussed under the corresponding problem area. This display of solutions is not to be perceived as the only options that could reconcile the resource problems in the study area.

Flooding

General

Floods kill people and destroy homes in many parts of the United States every year. Federal agencies estimate that an average of over 125 people die every year in the United States because of flooding, although losses vary widely from year to year. Property damages ranges into the billions each year, and has been rising in recent decades (Environmental Health Center 2003).

Vicinity of Wallace Lake

One of the major concerns in the project area is flooding associated with Wallace Lake. Wallace Lake was constructed as a large retention pond to hold water and release it at a rate that could be handled by the existing natural outflow. According to the U.S. Army Corps of Engineers, Wallace Lake is functioning as it was designed to do. The problem is that because of upstream development, within the floodplain and watershed, there is a greater volume of runoff, which is also flowing faster into the basin.

The U.S. Army Corps of Engineers reveals that the Wallace Lake Dam controls runoff from about 1 percent of the drainage area of the Red River below Denison Dam.

In May of 1975 the U.S. Army Corps of Engineers New Orleans District completed a Master Reservoir Regulation Manual on Wallace Lake (Cypress Bayou, Louisiana). The purpose of the manual was to present detailed information pertinent to Wallace Lake. Among other data this manual revealed that from the period of 1949 to 1969, the flood damage prevented by Wallace Lake was \$1,067,000 (\$5.5 million in present dollars).

In October 1989 a Reconnaissance Report on Wallace Lake Area (Boggy Bayou) was completed by the U.S. Army Corps of Engineers Vicksburg District. The Board of Commissioners, Caddo Parish, Louisiana, requested that the Corps investigate the flooding problems along Boggy Bayou. The decision was made to take the Wallace Lake area as the study area because of the public's views on flooding in the area. The purpose of the study was to identify the problem(s), determine if there is a solution, determine if the proposed solution would be in the Federal interest, and determine the local interests' willingness and ability to share in the funding of a subsequent feasibility study. Field

investigations and door-to-door surveys were made along each stream to determine the number of structures damaged and the extent of structural damages due to flooding. The number of structures damaged were of insufficient number to economically justify further study on all streams except Buchanan and Boggy Bayous. Several channel cross sections were taken along Boggy and Buchanan Bayous to supplement the existing cross sections. From the 1989 report several alternatives were considered: headwater – retention dams, levees, and channel improvement. Because of urban growth and terrain, only channel improvement was engineeringly feasible.

In fiscal year 1998 the Corps of Engineers received a work allowance of \$100,000 to conduct a reconnaissance study of the Wallace Lake area. The purpose of the study was to identify the flooding problems associated with the Wallace Lake area, investigate possible improvements to reduce or eliminate flood damages, determine if there is a feasible alternative for damage reduction, develop a Project Study Plan (PSP) to conduct further feasibility level studies, and identify a local sponsor to cost share the feasibility study. The study addressed two alternative solutions to the flooding problems, but the Corps noted that the dam was functioning as designed and that it does not cause flooding. Rapidly increasing urbanization in south Shreveport was compounding the problems.

Based on the Corps site surveys, 344 structures were identified within the Wallace Lake project area. Structures were divided into eight damage reaches based on their location along Boggy Bayou. The easement area identified those structures located in the flowage easement area below elevation 158.0 feet, NGVD), the “prohibited” area, and between 158.0 to 165.0, NGVD, the “owner-at-risk” area. Of the 344 structures identified in the project area, 103 structures were in the flowage easement area. Thirty-nine of the structures were in the “prohibited” area and 84 were in the “owner-at-risk” area. From this study the Corps of Engineers summarized that the flood damages incurred resulted in average annual benefits that were insufficient to justify a project of the magnitude required to appreciably reduce flood damages in the area. Also their evaluation illustrated that the majority of the damages and potential average annual benefits were derived from the 103 structures within the “prohibited” and “owner-at-risk” flowage easement area.

The Corps of Engineers stated that in order to further assist the functionality of the Wallace Lake project, they requested that the Caddo Levee District publish a notice in the Levee District’s journal or any other publication to inform property owners in the Wallace Lake area that their lands are subject to an easement and servitude, and additionally, that any dwelling or other structure maintained for human habitation will not have a first-floor elevation of less than 158.0 feet, NGVD. Any structure that includes a landfill below elevation 158.0 feet, NGVD, would require written permission from the Corps.

The alternatives given below were gathered from input at the public scoping meetings, private firms, grassroots organizations and governing entities.

Alternatives to Address the Wallace Flooding Problem

- Create several mini-retention ponds upstream along the bayous that feed Wallace Lake. Public linear parks, such as the Fant Parkway, along the various drainages with a series of ponds where weirs retaining water year round would create ponds for wildlife (fish, mammals, birds) and human enjoyment. Wetlands would develop with natural aquatics such as Louisiana iris, cypress trees, and lily pads, etc. These wetlands would become a teaching laboratory both to understand the natural and the man-made hydraulics. The linear parks or string of pearls would become a family recreational destination point for taxpayers and tourists alike. The proposed Wallace Lake linear parks could be linked with Shreveport's linear park (Fant Parkway) then Cross Bayou and along Cross Lake to the Cooper Road area; thus through paths and trails connect several lakes, parks, two universities, Sci-Port Expo, Barnwell, and other planned amenities along Cross Bayou.
- There is a place where an arm of Toledo Bend goes to the east and to the east of this arm over the drainage divide there is another co-linear drainage that flows east to Bayou Pierre. It may be possible to dredge between these two arms and allow the excess water from Broadmoor, Wallace Lake, and Bayou Pierre during high water to overflow into Toledo Bend. If this channel were made deeper there would be recreational potential. In theory one could then go by canoe from Shreveport down Bayou Pierre and into Toledo Bend. Or also with a portage over the dam from Wallace Lake with its proposed retention ponds upstream. There could even be a marina south of southeast Shreveport that could serve separate, but direct access to both Toledo Bend and the river. Should this alternative of cutting a channel to connect the two arms show to be infeasible, then a large siphon or inverted siphon could be investigated.
- Toledo Bend Reservoir provides important economic benefits to Louisiana and Texas, and provides valuable recreational opportunities to citizens of those States and to visitors from other locales. It also provides important habitat to many species of fish and wildlife. Certain areas of Toledo Bend are experiencing water quality problems. Therefore, any future considerations for the dredging proposal should carefully assess the potential effects of introducing contaminants and sediments from Wallace Lake and Bayou Pierre into the Toledo Bend Reservoir, since it already suffers from impaired water quality. Additionally, creation of a new channel could have adverse impacts on the hydrology and fish and wildlife resources of the study area. Some streams could experience significant reduction in flows and volumes, while others could experience increased flows, volumes, and turbidity (US Fish & Wildlife Service).
- Present openings (4) on the Wallace Lake Dam Spillway are 8 feet 3 inches wide and 3 feet high. The pool stage is 142 feet Mean Sea Level (MSL). The pool stage could possibly be lowered to 140 feet MSL by removing the block structures within the spillway

- Improve the channel capacity of Wallace Lake discharge streams by removing man-made debris and dense stands of young willows, cane, and greenbrier from within the streams below Wallace Lake to prevent tailwater effects on structure capacity.
- The sponsors in Caddo Parish could utilize FEMA's Property Acquisition Program (Buyouts). Buyout projects, while 75 percent funded by FEMA, are administered by the State and local communities. The Corps of Engineers have identified 344 residential and commercial structures as having potential impacts from flooding in the Wallace Lake area. The spillway of Wallace Lake is at elevation 158.0 feet, National Geodetic Vertical Datum (NGVD). Corps surveys show that 39 structures were constructed on lands below 158 feet, NGVD, and there were 84 structures constructed in the restricted easement areas at elevations between 158 and 165 feet, NGVD, at owner's risk. Buyouts would be strictly voluntary. No homeowners would be forced to relinquish their property. Homeowners who decide not to participate in the buyout might need to take risk reduction measures such as elevating their homes.
- Provide a survey at the 158 foot elevation to individual property owners to that each landowner knows where the flood easement is on their property

Lower Extremities of the River Basin

One of major items of concern in the south-central portion of the river basin is where Bayou Pierre traverses through Red River Parish. A local landowner in Red River Parish has been instrumental in preparing a slide presentation that depicts typical lack of maintenance cases associated with Bayou Pierre. There are areas that are choked with debris and silt bars and bridges with drift stacked against the upstream side. Debris removal from channels and bridge crossings. The Red River Levee & Drainage District does not have the financial resources, technical expertise and capabilities of alleviating or solving these problems in the lower extremities of the basin.

Alternatives to Address the Flooding Issues in the Lower Extremities of the River Basin were gathered at the public meetings.

- Build span bridges (no pilings). Between Red and De Soto Parishes the La Coute bridge is the worst. The highway 84 bridge in Red River clogs also.
- Monitor commercial timber operations (harvest tops instead of leaving them – utilize a chipper).
- Start at the confluence of Red River and Bayou Pierre and work upstream performing maintenance dredging resulting in a cross-sectional area capable of providing efficient flow. If applicable, maintenance dredging of channels will also include leaving gaps in the levee systems allowing overbank flow to enter adjacent wetlands for more storage of floodwaters.
- Look for alternatives that will result in restoration of the natural hydrology of the area to the highest extent possible. These include:
 1. Urging DOTD to implement measures that will consider effect on hydrology in the basin when performing highway or road improvements;

2. Reviewing all state and federal joint public notices for actions proposed to take place within the basin to reassure that the activity will not adversely impact existing drainage patterns;
3. Cooperating with landowners and land managers in the basin which have control over large water impoundments in order to expand equally beneficial measures that could result in a boost in flood water storage and improve aquatic resource production;
4. Provide information to local planning and zoning commissions about the importance of considering imperviousness when addressing new land development proposals.

Inadequate Floodplain Management Due to Rapid Development

Uncontrolled development can impact and aggravate almost all of the problems previously identified. Without some effort on the part of local officials, continued development without some foresight of the consequences will only worsen the resource problems of the area. Minimum floodplain regulations have been identified by the Federal Emergency Management Agency that are administered through the Flood Insurance Program. In addition, local floodplain regulations have been adopted by either the incorporated or unincorporated areas within the study area. Some floodplain regulations such as elevating above the 100-year flood elevation may prevent that structure from flooding but may have a long-term impact on the flood elevation as the floodplain is filled.

Local governments should mandate stormwater detention as a part of all-new subdivisions, malls, hospitals, shopping centers, industries, and other land uses beyond the 100-year floodplain. In existing subdivisions, local governments could purchase or acquire easements on remaining wetlands for stormwater storage. Design and rehabilitation of recreation facilities in the study area should include a stormwater detention component and extensive use of porous pavement. Communities in the entire Bayou Pierre study area would be benefited by reestablishing vegetative buffer strips or other best management practices along bayous and streams to slow runoff, trap sediment, and detain stormwater.

Information should be provided to local planning and zoning commissions about the importance of considering imperviousness when addressing new land development proposals. Imperviousness here is defined as the sum of roads, parking lots, sidewalks, rooftops, and other impermeable surfaces of the urban landscape. Intensive development activities inevitably accelerate runoff as a result of parking lots, streets, and rooftops. The total runoff from a one-acre meadow would fill a standard size office to a depth of about two feet (218 cubic feet). By way of comparison, if that same acre were completely paved, a one-inch rainstorm would completely fill an office, as well as the two next to it.

The community must regulate proposals for subdivisions. Subdividing is the division of a parcel of land into two or more separate lots for resale purposes. It is important to

review not only proposals for individual structures but also proposals for large scale developments, which might not even involve structural projects in the early stages. The laying out of lot and street patterns, the grading of land, and provision for utilities and storm water drainage will affect the flood risk to which later structural development will be exposed.

Section 60.3 (b) (3) of the National Flood Insurance Program Regulations states that all new subdivision proposals and other proposed developments (including proposals for manufactured home parks and subdivisions) greater than 50 lots or 5 acres, whichever is the lesser, include within such proposals base flood elevation data. By reviewing these proposals the community can require the developer to make any necessary revisions to minimize the flood damage potential. The items of greatest concern are public facilities and utilities and the drainage system, because of their role in determining the pattern and location of future development.

Floodplain Management Regulations

The regulatory requirements set forth by FEMA are the minimum measures acceptable for the National Flood Insurance Program (NFIP) participation. More stringent requirements adopted by the local community or State take precedence over the minimum regulatory requirements established for flood insurance availability. FEMA recommends communities take the following steps to help prevent damage and loss:

- Remove all debris from culverts, streams and channels to allow the free flow of potential floodwaters.
- Adopt policies now that will ensure that if flood destruction does occur, community redevelopment plans and actions will minimize future flood losses.
- Elevate electrical power stations and other utility facilities to ensure that vital services are not interrupted during flooding.

Mitigating Adverse Impacts

Mitigation includes any activities that prevent an emergency, reduce the chance of an emergency happening, or lessen the damaging effects of unavoidable emergencies. There are various methods of mitigation that could be utilized to offset the impact of development that exceeds local standards. Types of mitigation actions to reduce flood losses include those that modify human occupancy of the floodplain or watershed (usually a nonstructural measure) or modify the flood (usually a structural measure). Examples of implementation include enforcement of regulations and master plans, as well as delivery of programs and services. A no adverse impact strategy most likely will contain elements of each.

Table 10 presents the three negative effects that are most likely to result somewhere in the river basin when development activity takes place on floodprone land: increased flood stages, increased velocities, increased flows, and erosion and sedimentation. These are the problems that must be managed, mitigated, or prevented by the locality in order to achieve a no adverse impact floodplain or river basin. The examples are intended to demonstrate some remedial techniques but are not all-inclusive. Community approaches need to include development in the entire river basin, since any of this can create new floodprone land (Larson and Plasencia 2001).

Table 10. Some Adverse Impacts of Development on Floodprone Lands, Remedy Options to Mitigate Them, and Benefits/Limitations of those Options..¹

INCREASED FLOOD STAGES

Contributing Condition	Remedy	Comment
Floodplain encroachment	Implement no-rise floodway standard	Effectively used in many states and localities
Increased flow due to development (increased runoff from development will lead to higher flood stages)	Implement retention/detention standard	Commonly used to maintain existing flow, but must manage volumes and peaks or downstream flooding is increased
	Construct regional storage facilities	Commonly used to maintain existing flow, but must manage volumes and peaks or downstream flooding is increased
	Map to future-conditions hydrology	Does not address flooding of existing uses in floodplain
	Acquire land or flowage easements	Provides compensation for those impacted downstream
	Increased freeboard for constructed floors	Does not address flooding of existing uses in floodplain
	Channel or levee	Can move problem downstream

¹ This table was recreated from a study "No Adverse Impact: A New Direction in Floodplain Management Policy". It shows the relationship between development of floodprone lands and the impact of options on these lands.

INCREASED VELOCITY

Contributing Condition	Remedy	Comment
Floodplain encroachment	Manage velocity at upstream and downstream limits	Places requirement on those encroaching to match predevelopment velocities on adjacent properties
Increased flow due to development (Increased flows translate into higher velocities)	Implement retention/detention standard	Could be used to maintain preexisting velocity
	Construct regional storage facilities	Could be used to maintain preexisting velocity
	Map to future-conditions hydrology	Accepts that there will be increased velocities, provides an opportunity to protect new development. Does not address existing development
	Acquire land or flowage easements	Provides compensation for those impacted by increased velocity
Channelization and levees	Design so that velocities at upstream and downstream limits are returned to pre-project conditions	The impact to downstream properties is currently ignored in many flood control projects
	Utilize a restoration and setback levee approach	Provides structural flood protection while reducing adverse impacts to natural floodplain functions

INCREASED FLOWS

Contributing Condition	Remedy	Comment
Increased flow due to development	Implement retention/detention standard	Can immediately address adverse impact on the site of origin. Must also address volumes and peaks to avoid increasing downstream flooding.
	Construct regional storage facilities	Can be used to address existing problems. Must also address volumes and peaks to avoid increasing downstream flooding
	Manage to future – conditions hydrology	Accepts that there will be increased flows, provides an opportunity to protect new development. Does not address existing development
Floodplain encroachment (loss of natural floodplain storage)	Implement no-rise standard	Preserves floodplain storage that may be adversely impacted by future encroachment, naturally attenuates flood flows

EROSION & SEDIMENTATION

Contributing Condition	Remedy	Comment
Channel migration	Setbacks	Avoids inducing additional Erosion on other properties
	Bank stabilization	Can lead to instabilities in rest of floodplain although effective in some locations
Channel downcutting	Grade control structures;	Best used in highly impacted streams with significant infrastructure at risk
	Meander restoration	This method slows velocities and can lead to reduced channel downcutting while allowing for natural system restoration

Increased Flood Stages

One of the primary problems of managing floodplains and watersheds subject to development, as seen in Table 9, is increased flood stages (or depths). The primary existing control on future flood stages is the NFIP floodway standard, which allows flood depths to be increased up to 1 foot above nature's floodway as a result of floodplain encroachments. The impacts of this 1-foot increase in the flood stage on existing properties and future construction are not considered under the NFIP. The effect of the NFIP's 1-foot rise standard is that the future condition of the watershed or floodplain is given little or no consideration by states and communities.

To address this lack, some state and local governments require new buildings to be constructed 1–3 feet above the current flood elevation. Other tools that some are using include developing local regulatory floodplain maps premised on a fully developed or “future condition” watershed condition, utilizing local and regional basins to store excess runoff such that flood peaks are not increased; or some are exploring the concept of permanent easements that allows future overflow. Each of these techniques lends themselves towards either a regulatory or project based implementation, and are only some of the tools that could be considered (Larson and Plasencia 2001).

Increased Velocity

Whenever the discharge in a stream is increased without an offsetting increase in cross-sectional flow area, or when the cross-sectional flow area is decreased due to fill or development in the floodplain, velocities will increase. Increased velocity also commonly occurs when levees are installed, pinching in the river. The impact of these actions can be erosion from increased velocity and/or increased flooding or damage downstream. Approaches that limit or result in reduced floodplain encroachment that would increase velocities will prevent this problem. Retention or regional storage options that limit runoff from new development to the amount of discharge that existed before development will also prevent increased velocities (Larson and Plasencia 2001).

Increased Flow

A third area of concern is the management of increased flow. These increases are generally the result of paving of watersheds or the loss of in-stream storage due to filling or development. Communities continue to implement and evaluate retention and detention basins so that new development does not increase flow. If properly designed, retention/detention can limit downstream flood damage, and be readily blended into the developed landscape (Larson and Plasencia 2001).

Need for a Local Plan

The tendency in floodplain management to date has been to manage part of the impact while ignoring the rest. The net result is that well-intended actions are leading to unmanaged reactions in the system. A well-done plan would include a technical analysis to quantify current and future conditions; it would incorporate mitigation techniques to minimize impacts; it would identify implementation measures to manage all of the hazard factors identified; it would include strong citizen involvement so the plan is equitable; and it would ultimately provide a vision for future use of the community's land within and outside the floodplain (Larson and Plasencia 2001).

Drainage Impact Study

The City of Shreveport and the Town of Keithville should pass joint resolutions requiring drainage impact studies for all new development. The purpose of a Drainage Impact Study is to identify potential drainage problems that may occur as a result of a proposed development and to determine theoretical solutions to mitigate any adverse impacts. These resolutions should stipulate the method to be used in each analysis. Not only should the site-specific impacts be analyzed but the compound effect of future development. This analysis should consider both upstream and downstream effects and mitigation applied accordingly. One possible tool that is available to make these analyses in the upper reaches is the Bayou Pierre Diversion Channel Feasibility Study that was done by Balar Associates, Inc., and Demopoulos and Ferguson, Inc. Some engineering modeling could be done. The model could be used to predict changes and the associated impacts before a measure is implemented. Proper use of the model and drainage impact studies can prevent an increase in flood risks.

Water Quality and Watershed Protection

Most of the problems identified in the Bayou Pierre River Basin area are linked to one another. Communities across the nation are finding that their water resources are degrading in response to growth and development. Communities such as the ones in the study area quickly find many reasons to protect local watersheds whether it is because of economic benefits, recreation, flood prevention, scenery or the overall quality of life. In many cases, if one problem is solved it will improve or solve another problem. The following alternatives are offered to enhance water quality in the study area.

Reduce Gully Erosion

Installation of measures to stop gully erosion will also improve water quality. The suspended solids and attached pollutants will be reduced.

Utilize Best Management Practices

Continue to implement and monitor the results of existing and additional Best Management Practices (BMPs). BMPs describe any practice or routine procedure designed to reduce pollutants that can be picked up by runoff or reduce the amount of

pollutants in the run-off before they reach a body of water. BMPs are designed to reduce pollutants such as sediments, nutrients, heavy metals, bacteria, pesticides, or any form of contaminating pollutants in run-off. While there are numerous BMPs that are being implemented within the agricultural sector, there are many more that are applicable, as well as those suited to urban areas. Some examples of BMPs include pollution source controls (proper fertilizer application techniques), conservation tillage, grade stabilization structures, temporary silt fences around construction sites, and sediment retention or detention ponds. In many cases BMPs cost little to nothing to implement and are incorporated into normal operations.

Timber Harvesting

Private landowners should consider utilizing contractors who have completed 30 hours of instruction in the Louisiana Master Logger Program. Individuals who have completed the program will have undergone training in timber harvesting and transportation, OSHA regulations, harvesting planning & best management practices, business management for professional contract loggers and erosion control.

Some Best Management Practices for felling trees in the study area to consider include:

- When possible, trees should be directionally felled away from water bodies.
- Remove only tops and limbs that have fallen into any water body during harvesting.
- Inspect all stream courses to be sure they are free from excessive debris.

Restore and Preserve Wetlands

Encourage the preservation of existing wetlands and the restoration of converted wetland areas. Wetlands serve as detention areas that filter pollutants from the water body as it overflows. Wetland development can be one through such programs that offer incentives such as WRP, CRP, etc., and voluntary restoration or enhancement efforts in which there is no compensation to the landowner. These programs will be discussed in more detail under the wetland section of the report.

Utilize Floodplain Management Measures

Implement and enforce measures that assure development in floodplains is done in such a manner that the integrity of the floodplain is maintained. Floodplains provide areas where floodwaters are detained or stored when the channel conveyance system is exceeded. These detention areas allow suspended sediments and other contaminants to settle. Where possible, grass areas and earthen open channel drains should be utilized in lieu of concrete and curb and gutter drainage to retard the flushing of pollutants into the receiving water body.

TMDL Implementation

The TMDL will be established for the study area will contain the key elements outlined below:

- Waterbody name and location
- Identification of the pollutant
- The water quality standard for the waterbody
- Amount of pollutant allowable to meet standards (pollution budget)
- Load reduction needed to meet standards
- Sources of the pollutant
- Wasteload allocation for point sources
- Load allocation for runoff (nonpoint sources) and other sources of pollution
- Margin of safety
- Consideration of seasonal variation
- Public comment period
- EPA review and approval

When this area's TMDL is established, the State of Louisiana must provide reasonable assurances that all affected sources will be able to meet their allocated load reductions. For point sources, reasonable assurance is to be provided through the Louisiana Pollutant Discharge Elimination System (LPDES) permits. For nonpoint sources, reasonable assurance will consist of a watershed implementation plan, which describes the types of voluntary actions, or Best Management Practices (BMPs), that are necessary to achieve compliance and the delivery mechanism that will be used to ensure their implementation throughout the watershed.

For control of pollutants from nonpoint sources, BMPs will continue to be implemented through the current nonregulatory, cooperative program. LDEQ will closely monitor BMP implementation and provide advice and assistance in pursuing innovative methods in the control of nonpoint source pollutants.

The success of the TMDL program largely resides with the agricultural, silvicultural, industrial and municipal facilities, and urban communities within the Bayou Pierre study area. Without the cooperation from these stakeholders, TMDL implementation will not be successful.

Erosion and Sedimentation

Communities often permit development that causes erosion or sedimentation problems at the site of a development or on other property along the stream. Master plans for all development in the watershed may not exist, thus leading to unintended impacts. This is analogous to providing enough landfill space for new growth. Channelization and bank stabilization designs generally are measured for site-specific performance, but their impacts on channel geomorphology are often overlooked. In some cases this has led to

the creation of instabilities, causing channel downcutting and bank erosion (Larson and Plasencia 2001).

Groundwater Recharge

The river basin study area covers parts of three aquifers in Northwest Louisiana. These aquifers have been declining due to subsurface withdrawal for industrial and domestic use. One of the potential solutions to reduce withdrawal rates is to utilize surface water for industrial and agricultural uses where available. This requires projects that move surface water into the bayous and other streams to provide a consistent supply for these user groups. See Irrigation below for a potential solution to reducing groundwater withdrawal.

Irrigation

In order to utilize water from the Red River, a possible alternative could be to construct a pump station or stations in the Red River for the purposes of moving irrigation water into the study area utilizing Bayou Lumbré, Caspiana Bayou and Grand Bayou. An extensive engineering analysis would have to be done for this alternative. Factors that would have to be considered are:

- Economic feasibility. Cost would be in the millions of dollars
- A pumping station with a capacity of 145 cubic feet per second is necessary to irrigate about 5,000 acres.
- Weirs would have to be constructed in the bayou(s) to maintain irrigation pools.
- Woody vegetation and silt bars that obstruct flow would have to be cleared in order to facilitate the flow of irrigation water.

Beneficial Programs

In lieu of or in conjunction with the structural measures that have been listed with the alternatives, non-structural alternatives, where applicable, may be preferred. These alternatives may or may not provide monetary and/or tax incentives to the landowners for allowing their property to revert to wetlands or retain their floodplain traits. A few of these programs that provide flood protection benefits will be briefly presented within this section and discussed in detail in the alternate solutions listed under Loss of Wetland Resources.

Conservation Reserve Program (CRP): This program is used to remove land from agricultural production that will yield the highest environmental benefits. Areas subject to flooding may qualify for this program. Under CRP, the Farm Service Agency (FSA) will cost-share with landowners to implement an approved conservation plan and pay landowners annual rental payments for 10 to 15 years to maintain those practices.

Flood Risk Reduction Program: This program authorizes voluntary contracts that provide one lump-sum payment to landowners that farm land with high flood potential. This

payment will equal 95 percent of the seven-year agricultural market transition payments to offset estimated federal outlays on frequently flooded land. In return, landowners agree to comply with applicable wetlands and highly erodible land requirements and to forgo commodity loans, crop insurance, conservation payments, and disaster payments. This program is administered through FSA.

Wetlands Reserve Program (WRP): This is a voluntary program that offers landowners financial incentives to restore and protect wetlands on private property. Landowners who participate in WRP record a conservation easement on their property or enter into a restoration agreement in exchange for land payments and/or cost-share payments for restoration practices. This program is administered through NRCS.

Flood Flow Easements: While there is no known use of such of a program in this state except in the case of lakes or reservoirs, the importance of such a program should not be underestimated. While wetlands are very important to the ecosystem, equal or more important are floodplains. While wetlands and floodplains are generally characterized by a hydric or wet condition, in many cases a floodplain is void of wetland characteristics such as vegetation. Floodplains provide temporary reservoirs or storage areas for excess runoff and provide many of the same benefits of wetlands such as aquifer recharge and water quality improvement. Local units of government should solicit assistance in developing and implementing a program where flowage easements associated with the 100-year floodplain can be obtained and the private landowner compensated to retain or restore this easement area.

Recreation

The study area offer an excellent potential for supplying a significant part of the resource-oriented and water-based recreational demand. Some of the demand for water-based recreational activities can be met by enhancement of existing water bodies through improved management, access, control, and water quality, removal of obstructions, and development of adjacent recreational facilities. The State Parks and Recreation Commission and the Louisiana Department of Wildlife and Fisheries can satisfy a substantial portion of the recreational demand if provided with the necessary support. Increased financial support will give these agencies the opportunity to expand their programs and properly maintain existing facilities.

Aquatic Health of Smithport and Clear Lakes

Environmentally sound and cost-effective management decisions should be the basis of any aquatic weed control program. All control measures will affect the environment, so it is important to consider the intended use of the water body. Physical constraints such as shallow water or obstacles can impair herbicide applications. Water quality variables such as total alkalinity or the possibility of dissolved oxygen depletions are important considerations. Potential impacts on fish and wildlife populations must also be considered. As with any alternative measure, the economic feasibility is a major factor. Some alternatives that could be considered include:

- **Drawdown.** Drawdown is limited to lakes with adequate water control structures and a reliable source of water for refilling the lake. Drawdowns are usually conducted during winter to expose plants to drying and freezing. The advantages include low cost as well as oxidation and consolidation of sediment. Drawdowns also increase options for chemical controls because some chemicals are more effective when applied to dry water bottoms. One disadvantage of drawdowns is that they may reduce desirable species and allow tolerant species to spread further. There may also be some loss of recreational benefits such as duck hunting and spring fishing.
- **Chemical Control.** There are about 200 herbicides registered in the United States but only 10 are labeled for aquatic sites. These chemicals can effectively control aquatic weeds. A consideration is that as dead aquatic plants decay, oxygen in the surrounding water is used in the process. If large quantities of plants are killed with one treatment, dissolved oxygen in the water may be reduced to the point that fish and other aquatic organisms die. Therefore, it is usually desirable to treat only a portion of a weed problem at a time. This allows the body of water to recover lost oxygen before subsequent treatments. The possibility of low oxygen becomes more serious as water temperatures rise in late summer. If possible, weed problems should be dealt with when water temperatures are between 70 and 80 degrees F.

Fish and Wildlife Habitat

A major planning objective, is that the cooperative watershed study identify ways to maintain or enhance aquatic and terrestrial habitat diversity along Bayou Pierre. Based on the current state of knowledge and growing public interest in preserving and restoring natural aquatic ecosystems, any plan that further modifies Bayou Pierre for flood damage reduction also should include measures to maintain fish and wildlife habitats characteristics of natural stream ecosystems. Such habitat elements could be provided by designing control structures to preserve flows downstream of dams or weirs, adding structural modifications for fish movement, rehabilitating pools and slackwater areas, placing in-stream sources of coarse woody debris, and maintaining or creating habitat diversity. Riparian habitat losses should be minimized as much as practicable by depositing excavated spoil material in cleared uplands, and by restoring riparian floodplains through reforestation of bottomland hardwood species.

Wetlands and Associated Resources

Wetlands provide areas for flood storage, filtering where water quality is improved, aquifer recharge, habitat for wildlife, and recreation. As stated above, loss of wetlands can be attributed to changes in land use associated with development and the demand for agricultural products. There are numerous programs that are available to private landowners that promote the restoration and enhancement of wetlands. Some of these programs provide monetary incentives to the landowner to maintain and restore wetlands. In addition, there are other means to enhance and preserve wetland areas. Some of these alternate solutions are shown below.

The following represent some of these programs administered by USDA and FWS that create, restore, enhance, or protect wetland areas.

Conservation Reserve Program (CRP): This program which is administered by Farm Service Agency (FSA) was briefly discussed under Flooding Alternatives. The 2002 Farm Bill enhances the CRP to better conserve and improve natural resources. The Commodity Credit Corporation and the FSA focus on enrolling land that will yield the highest environmental benefits when taken out of production. CRP offers annual rental payments and cost-share assistance to farmers to establish long-term conserving covers (e.g., grass and trees) on eligible land. Contracts are for a minimum of 10 years and maximum of 15 years.

CRP Wetland Enrollment Pilot Program: This program allows enrollment of farmed wetland acres in CRP. Contract can include up to 10 acres of wetland, although not more than 5 would be eligible for payment. Buffer acreage is limited to 3 times the wetland acreage.

CRP Continuous Sign-Up: This program is for high priority practices and allows enrollment of land in riparian buffers, filter strips, grass waterways, and other high-priority practices without competition. Producers may enroll entire fields as buffers through the continuous sign-up when more than 50% of the field is eligible (through continuous sign-up) and farming is infeasible on the remainder of the field. Payments on the remaining acreage are limited to general sign-up rates.

Wetlands Reserve Program (WRP): This voluntary program is administered by NRCS and enables the Secretary of Agriculture to purchase long-term or permanent easements and provide cost sharing to producers who agree to restore wetland on agricultural land. Restoring wetlands wildlife habitat is a priority. As previously mentioned wetlands are to be restored through permanent easements, 30-year easements, restoration cost-share agreements, or any combination of these options. Lands accepted into the program are subject to a Wetland Reserve Plan of Operation developed by NRCS, the landowner, and FWS which identifies practices to restore the functional values of the wetland (tree planting, ditch plugs, levee breaches, etc.) Compatible uses of lands encumbered by conservation easements usually include responsible timber harvest, hunting and fishing, or leasing of hunting and fishing. Eligible lands include farmed wetland cropland, prior converted cropland, farmed wetland pasture, riparian wetlands, hydrologically degraded rangeland, pasture or forested areas, limited buffer areas and certain wetlands previously restored under other programs.

Wildlife Habitat Incentives Program: Wildlife Habitat Incentives Program (WHIP) is a conservation program authorized by the 1996 Farm Bill. The program provides technical assistance and cost-share payments to landowners interested in improving upland wildlife habitat, wetland wildlife habitat, threatened or endangered species habitat, fisheries and other wildlife habitat. NRCS administers the program with input from FSA, FWS, LDWF, and local Soil and Water Conservation Districts. Landowners may receive cost-

share payments amounting to 75 percent of the cost of establishing eligible conservation practices, but total payments may not exceed \$10,000 per individual. NRCS will develop a Wildlife Habitat Development Plan of Operations which identifies necessary conservation practices, baseline wildlife habitat conditions, and a schedule of implementation and maintenance. Cost-shared conservation practices must be maintained for a minimum of 10 years.

Partners for Wildlife: Through this program the FWS provides technical and financial assistance for habitat restoration and enhancement on private lands. The emphasis of this program is to restore the hydrology and vegetation on altered wetland sites toward the original or historic wetland condition. Management treatments that stall or prevent the natural succession (such as creating moist-soil impoundments on former bottomland hardwood areas) must be limited to no more than 30 percent of the project site. Landowners can be reimbursed for up to 100 percent of the cost of restoration practices. However, for most projects the maximum amount that can be expended on a person's property per year is \$10,000. Although not mandatory, some financial or in-kind contribution from the landowner may aid in the selection of the project by the FWS Private Lands Committee that ranks project applications. Project implementation is contingent upon completion and signature of a 10-year or longer Wildlife Development Agreement between the landowner and FWS that specifies each party's commitment to the project. When restoration requires a long period to accrue, such as reforestation of bottomland hardwoods, longer agreements of 25-years or more are typically negotiated.

Seasonally Flooded Wetland Easements: Solicit Federal and State agencies to establish and implement a program where private landowners were compensated to retain overflow floodplain areas to serve as storage areas and; where applicable, allow these areas to convert to wetlands. This program would be similar to the Flood Risk Reduction Program discussed under the flooding section with the exception it would not be limited to farmland.

Retention Type Grade Stabilization Structures: In applicable areas treat gully erosion with retention type grade stabilization structures. This type of structure can create a pond area above the inlet pipe. This pond will serve as a shallow water area and offer the benefits of such a wetland type area. In addition, it will provide a watering area for wildlife and livestock. This type retention area should be developed in rural pasture and woodland areas.

Education and Public Outreach Program

Public entities and grassroots organizations should develop a public awareness program to educate the public on the rewards of properly managing soil, water, and related resources. Included should be such topics as wetland restoration and preservation, point and nonpoint pollution, etc.

The program should include public seminars and workshop, printed stickers and brochures, as well as school projects such as poster and essay contests. Ideas and

suggestions for this program can be obtained from federal agencies such as EPA, NRCS, and the Louisiana Cooperative Extension Service; state agencies such as LDEQ and LDAF; local groups such as the chamber of commerce; and local businesses, corporations, and industries that are always seeking ways to improve their public relations. In many cases these groups can provide both financial and technical support.

Bayou Pierre Coalition

In order to address the flood concerns associated with the lower extremities of Bayou Pierre, a Bayou Pierre Coalition composed individuals from Caddo, De Soto, Red River and Natchitoches Parishes could be organized. The coalition could seek strategies to fund engineering surveys of the lower extremities of Bayou Pierre

Potential Partners

Solving the resource problems within the Bayou Pierre River Basin Study area would be a comparatively effortless task if there were a boundless source of money available to fund corrective measures within the study area. However, with only limited funds available from local, state, and federal sources, implementing the proposed alternative solutions will require a united effort by private landowners, local, state, and federal government entities; and developers and businesses within the project area. Possible funding sources that could be utilized in the Bayou Pierre Study area are listed in Appendix C. The accomplishment of implementing land treatment options such as BMPs, flooding issues, wetland and floodplain restoration, etc., will rely greatly on a voluntary effort by private landowners. The following groups or agencies are a few sources that administer programs that provide financial and/or technical assistance to solve resource problems. A more specific listing of the sponsors, and resource entities can be found in Appendix C.

Federal Agencies

Farm Service Agency (FSA): FSA administer farm commodity, crop insurance and conservation programs for farmers and makes farm ownership and operating loans. FSA programs are primarily directed at agricultural producers or, in the case of loans, at those with farming experience. State and parish FSA committees whose members are actively engaged in farming or ranching administer and oversee FSA programs and field activities.

Natural Resources Conservation Service (NRCS): NRCS works directly with private landowners and land users (cooperators) to help them protect their natural resources. NRCS personnel work with land users on agricultural land, forestland, wetlands, and other lands to plan, design, and install soil and water conservation practices that reduce erosion and improve water quality. They work in close cooperation with soil and water conservation districts through field offices to provide the technical assistance cooperators need. Using its wide variety of expertise regarding soils, vegetation, wildlife, and engineering, NRCS offers conservation planning to landowners for purposes of

conservation compliance or development of specific cooperator needs. Plans can be developed to reduce erosion, improve water management and conservation, develop and enhance wildlife habitat, etc. These services are provided to the cooperator at no expense.

Financial assistance is available to land users through the Watershed Protection and Flood Prevention Act (PL-83-566). Once a watershed project is approved for operation within an area, cost share is available to landowners to implement measures that benefit water quality, wildlife, and reduce flood damages.

Louisiana Cooperative Extension Service: The Louisiana Cooperative Extension Service (LCES) is part of the land grant college system and is the educational arm of USDA in Louisiana. Administered through the Louisiana State University Agricultural Center, LCES has offices in all parishes. Each office is staffed with Extension agents with expertise in agriculture and natural resource conservation and management. The LCES field staff is supported by specialist who helps coordinate parish outreach activities. These specialists have expertise in wetland resources, wildlife, forestry, aquaculture, agriculture and natural resources, economics, agronomy, crop production, water quality, environmental education, etc. LCES parish agents provide educational information to all agricultural and natural resource user groups through numerous outreach techniques. Educational services are free and available to everyone.

Fish and Wildlife Service (FWS): The FWS provides technical and financial assistance to landowners to benefit wildlife and waterfowl habitat. FWS also coordinates with other agencies by providing technical assistance to those agencies in wildlife habitat creation and restoration projects. FWS helps to meet habitat restoration needs on private lands in the Bayou Pierre Basin through the Partners for Fish and Wildlife Program. The Partners program provides technical and financial assistance to private landowners to restore and enhance fish and wildlife habitat on their property, with a focus on bottomland hardwoods reforestation and restoration of historic hydrologic conditions. FWS expects the Partners program to become more active in the Red River and Bayou Pierre watersheds with establishment of the Red River NWR.

U.S. Geological Survey (USGS): USGS collects information on surface and ground water and publishes this information for public information. They also establish and maintain stream-gauging stations that record stage and discharges at many locations throughout the United States. USGS works closely with LADOTD in both ground and surface water studies and publications.

U.S. Army Corps of Engineers (USACE): The USACE Vicksburg District encompasses 68,000 square miles in three states, with a \$220-million annual resources program. The Vicksburg District current missions include flood control, water supply, navigation, emergency operations, hydropower, water quality recreation and environmental resources. Vicksburg's multi-disciplined team of engineers, planners, and environmental, municipal, and recreation specialist are also available, as needed, for Federal and state customers on a reimbursable basis. One of the largest civil works districts in the nation;

Vicksburg is a center of expertise for many engineering and environmental capabilities. New programs allow the Corps to partner with local agencies and groups to meet their engineering needs.

Federal Emergency Management Agency (FEMA): A branch of the Environmental Protection Agency, FEMA has ten regional offices. Each region serves several states, and regional staff work directly with the states to help plan for disasters, develop mitigation programs, and meet when major disasters occur. FEMA also has programs that help communities prepare for natural disasters in order to reduce possible catastrophic damage. The Bayou Pierre River Basin is located in FEMA's Region VI.

Resource Conservation and Development (RC&D): RC&D's were established in the Agriculture Act of 1962 to provide a program that empowered rural people to help themselves. The focus on local direction and control has made RC&D one of the most successful programs of the federal government. The Bayou Pierre Basin is served by the Twin Valley RC&D Council.

State Agencies

Louisiana Department of Agriculture and Forestry (LDAF): The Louisiana Department of Agriculture and Forestry provides education and financial assistance to landowners and communities.

Office of Soil and Water Conservation (OSWC): The OSWC is designated as the state agency that cooperates with NRCS to carry out federal conservation programs. The OSWC provides technical assistance and administrative support to the 43 statewide soil and water conservation districts. These are local units of government through which landowners and landusers receive technical assistance to plan and apply conservation measures on their lands to conserve soil, water, wildlife habitat and related resources. The OSWC works closely with other state and federal resource management agencies that serve to broaden and extend resource management practices on the landscape. The OSWC is responsible for the preparation and establishment of BMPs to achieve environmental compliance in various agricultural operations. Conservation districts serve as local sponsors for PL-566 Watershed projects.

Louisiana Office of Forestry (LOF): LOF provides professional technical assistance to private landowners regarding management of existing timber sales, establishment of new stands and marketing timber. Properties of any size are eligible for LOF assistance in developing a general forest management plan and in establishing new stands of trees. For ownership of fewer than 200 acres, LOF will assist the landowner with marking timber and conducting timber sales. LOF implements the Stewardship Incentive Program (SIP) to landowners which provides up to \$10,000 per year for cost-shared practices for a 10 year contract period.

Louisiana Department of Transportation (LADOTD): LADOTD provides technical and financial assistance to local units of government through the PL-566 watershed program

administered by the NRCS. The water resources section of LADOTD absorbed the Office of Public Works that provided technical and financial assistance for many public works projects such as airports, drainage, levees, etc. The water resources section in each LADOTD District Office has planning and design records, and, in some cases construction and “as built” drawings of many of these projects. In many cases LADOTD financial assistance is provided to replace inadequate road crossings within watershed projects. LADOTD has administered construction contracts for NRCS on watershed projects in the state of Louisiana. In addition, LADOTD provides technical assistance to local units of government such as police juries and levee and drainage districts.

Louisiana Department of Environmental Quality, Office of Water Resources (LDEQ-OWR): The Office of Water Resources is responsible for managing the quality of the state’s ground and surface water. LDEQ-OWR monitors and manages a network of water quality stations throughout the state. Water samples are collected on set time intervals and analyzed for pollutants such as pesticides, herbicides, nitrates, suspended solids, etc. and conveys this information to the public. LDEQ-OWR is responsible for administering the U.S. Environmental Protection Agency’s Section 319 program of the Clean Water Act. Section 319 deals with nonpoint pollution. LDEQ-OWR works with NRCS and local soil and water conservation districts in implementing demonstration projects on private lands that will reduce nonpoint pollution.

Louisiana Department of Wildlife & Fisheries (LDWF): LDWF offers technical assistance regarding a wide variety of fish and wildlife and their habitats. For general information on fish ponds, non-game species, upland game, waterfowl, deer, aquatic weed control, urban and backyard nuisance animal control, wildlife habitat creation and management contact the nearest LDWF District Office found in Appendix A. Programs that are administered through LDWF include: Guide Services, Education Programs, Nongame Programs/La. Natural Heritage Program, New Interactive Website for Kids, Hide Quality RFP 2002, Fur and Alligator Advisory Council, Coastwide Nutria Control Program, and the Louisiana Wildlife and Fisheries Foundation.

Local Organizations and Associations

Red River Valley Association (RRVA): The Red River Valley Association is a nonprofit; member supported organization dedicated to the development of the land water resources of the Red River Basin. With lobbying as its primary function its strength is from the voice of its members which are chiefly from the Red River Valley states of Texas, Oklahoma, Arkansas, and Louisiana. Only through the RRVA’s lobbying efforts have milestone projects such as navigation, chloride control, levee and bank stabilization, and many other worthwhile enterprises along the Red River became reality. Some of the objective of the RRVA include: 1) Enhancing the drainage systems and control the effects of flooding, as well as agricultural related projects; 2) Enhancing water quality through chloride control; and 3) Aiding in environmental enhancement efforts such as reforestation, wetland preservation, and wildlife aquatic refuge construction. The RRVA is eager to work with local, state, and federal entities in securing funds to implement projects that will correct resource problems within the valley.

Soil and Water Conservation Districts (SWCDs): In Louisiana, SWCDs have the responsibility of conserving Louisiana's soil and water resources since 1938, when the Louisiana Legislature passed the Soil Conservation District Law, Act 370. The objectives, as stated in the law, are to provide for conservation of the state's soil and water resources, control and prevent soil erosion preserve wildlife, protect public lands, and promote the health, safety, and general welfare of the people of the state. The Act recognized Louisiana's farm, grazing, and other crops for domestic use and export. Other inventories made on the status and condition of natural and related resources furnish data for resource analyses and evaluation, programming, and planning at the state and national levels. The Bayou Pierre River Basin has five SWCDs: Caddo, De Soto, Natchitoches, Red River, and Sabine. Their principle function is to provide technical assistance to local landowners in implementing measures that will conserve soil, water, and other related resources. In addition, they serve as local sponsors for federal and state funded projects. These SWCDs meet monthly and meetings are open to the general public.

Levee and Drainage Districts: The levee and drainage districts are charged with providing and maintaining levee-toe drainage and levee maintenance for a large part of the river basin. They work with other local, state, and federal agencies and private landowners in this endeavor. The rules and regulations of the levee and drainage districts are designed to promote the most effective use of all lands, waters and facilities governed by the districts. The Natchitoches Levee and Drainage District and the Red River Levee and Drainage District are two of the local governing bodies as well as sponsors of the Bayou Pierre Cooperative River Basin Study.

Police Juries: Louisiana is unique in the nation in that it has parishes that are governed in most cases by police juries. The jury system provides government close to the people. The jury performs the legislative functions of enacting ordinances, establishing programs and setting policy. It is also an administrative body in that it is involved in preparing the budget, hiring and firing personnel, spending funds, negotiating contracts and in general, directing the activities under its supervision. The Police Jury of Natchitoches Parish, Red River, Sabine, De Soto, and the Caddo Parish Commission are five local governing bodies as well as sponsors of the Bayou Pierre Cooperative River Basin Study.

Civil Rights Compliance

A civil rights impact analysis was performed as required by Departmental Regulation 4300-4. The purpose of this regulation is to assure that no individuals that are socially or economically disadvantaged, minorities, women, or persons with disabilities are negatively impacted by any policy, program, or action administered by the U.S. Department of Agriculture (USDA). The civil rights policy for USDA and its programs states:

“No person or group shall be discriminated on the basis of race, color,

sex, national origin, religion, age, disability, or marital or familial status in any employment practice or in any program conducted or assisted by the Department of Agriculture.”

Under this policy “major civil rights impacts” are those consequences of proposed policy actions which, if implemented, will negatively and disproportionately affect minorities, women, or persons with disabilities who are employees, program beneficiaries or applicants for employment or program benefits in USDA-conducted or assisted programs by virtue of their race, color, sex, national origin, religion, age, disability, or marital or familial status.

The civil rights impact analysis weighed the problems and recommended alternate solutions presented and concluded the overall impact to all people within the study area should be of a positive nature.

All alternate solutions whether offered through actual construction activities or government incentive programs administered directly to private landowners shall be offered in an equal and unbiased manner to all people without regards to race, color, national origin, age, disability, marital or familial status. Implementation of recommended alternate solutions should enhance the natural resources within the area, which in turn, will improve and sustain the quality of life of all people within the Bayou Pierre River Basin area.

APPENDIX B. Biological Resources.

FISH POSSIBLY OCCURRING WITHIN BAYOU PIERRE RIVER BASIN

Common Name

Scientific Name

Chestnut lamprey
 Shovelnose sturgeon
 Paddlefish
 Alligator gar
 Spotted gar
 Longnose gar
 Shortnose gar
 Bowfin
 American eel
 Skipjack herring
 Gizzard shad
 Threadfin shad
 Goldeye
 Mooneye
 Grass pickerel
 Chain pickerel
 Mexican tetra
 Goldfish
 Grass carp
 Common carp
 Cypress minnow
 Central silvery minnow
 Eastern silvery minnow
 Speckled chub
 Flathead chub
 Silver chub
 Gravel chub
 Golden shiner
 Pallid shiner
 Emerald shiner
 Blackspot shiner
 Ghost shiner
 Ironcolor shiner
 Striped shiner
 Pugnose minnow
 Beautiful shiner
 Ribbon shiner
 Bluehead shiner
 Red shiner
 Taillight shiner

Ichthyomyzon castaneus
Scaphirhynchus platyrhynchus
Polyodon spathula
Atractosteus spatula
Lepisosteus oculatus
Lepisosteus osseus
Lepisosteus platostomus
Amia calva
Anguilla rostrata
Alosa chrysochloris
Dorosoma cepedianum
Dorosoma petenense
Hiodon alosoides
Hiodon tergisus
Esox americanus
Esox niger
Astyanax mexicanus
Carassius auratus
Ctenopharyngodon idella
Cyprinus carpio
Hybognathus hayi
Hybognathus nuchalis
Hybognathus reginus
Hybopsis aestivalis
Hybopsis gracilis
Hybopsis storeriana
Hybopsis x-punctata
Notemigonus crysoleucas
Notropis amnis
Notropis atherinoides
Notropis atrocaudalis
Notropis buchanani
Notropis chalybaeus
Notropis chrysocephalus
Notropis emiliae
Notropis formosus
Notropis fumeus
Notropis hubbsi
Notropis lutrensis
Notropis maculatus

Fish (continued)

Common Name

Scientific Name

Chub shiner
Silverband shiner
Weed shiner
Redfin shiner
Blacktail shiner
Mimic shiner
Fathead minnow
Bullhead minnow
Creek chub
River carpsucker
Quillback
Blue sucker
Creek chubsucker
Lake chubsucker
Smallmouth buffalo
Bigmouth buffalo
Black buffalo
Spotted sucker
Blacktail redhorse
Blue catfish
Black bullhead
Yellow bullhead
Channel catfish
Black madtom
Tadpole madtom
Freckled madtom
Brown madtom
Flathead catfish
Pirate perch
Blair's starhead topminnow
Golden topminnow
Blackstripe topminnow
Blackspotted topminnow
Mosquitofish
Inland silversides
Yellow bass
Striped bass
Banded pygmy sunfish
Green sunfish
Warmouth
Orangespotted sunfish
Bluegill

Notropis potteri
Notropis shumardi
Notropis texanus
Notropis umbratilis
Notropis venustus
Notropis volucellus
Pimephales promelas
Pimephales vigilax
Semotilus atromaculatus
Carpiodes carpio
Carpiodes cyprinus
Cycleptus elongatus
Erimyzon oblongus
Erimyzon sucetta
Ictiobus bubalus
Ictiobus cyprinellus
Ictiobus niger
Minytrema melanops
Moxostoma poecilurum
Ictalurus furcatus
Ictalurus melas
Ictalurus natalis
Ictalurus punctatus
Noturus funebris
Noturus gyrinus
Noturus nocturnus
Noturus phaeus
Pylodictis olivaris
Aphredoderus sayanus
Fundulus blairae
Fundulus chrysotus
Fundulus notatus
Fundulus olivaceus
Gambusia affinis
Morone chrysops
Morone mississippiensis
Morone saxatilis
Elassoma zonatum
Lepomis cyanellus
Lepomis gulosus
Lepomis humilis
Lepomis macrochirus

Fish (continued)

Common Name

Dollar sunfish
Longear sunfish
Redear sunfish
Spotted sunfish
Bantam sunfish
Spotted bass
Largemouth bass
White crappie
Black crappie
Western sand darter
Scaly sand darter
Mud darter
Bluntnose darter
Creole darter
Fountain darter
Swamp darter
Slough darter
Harlequin darter
Goldstripe darter
Cypress darter
Redfin darter
Backwater darter
Logperch
Blackside darter
Dusky darter
River darter
Sauger
Freshwater drum
Striped mullet

Scientific Name

Lepomis marginatus
Lepomis megalotis
Lepomis microlophus
Lepomis punctatus
Lepomis symmetricus
Micropterus punctulatus
Micropterus salmoides
Pomoxis annularis
Pomoxis nigromaculatus
Ammocrypta clara
Ammocrypta vivax
Etheostoma asprigene
Etheostoma chlorosomum
Etheostoma collettei
Etheostoma fonticola
Etheostoma fusiforme
Etheostoma gracile
Etheostoma histrio
Etheostoma parvipinne
Etheostoma proeliare
Etheostoma whipplei
Etheostoma zoniferum
Percina caprodes
Percina maculata
Percina sciera
Percina shumardi
Stizostedion canadense
Aplodinotus grunniens
Mugil cephalus

AMPHIBIANS POSSIBLY OCCURRING WITHIN BAYOU PIERRE RIVER BASIN

Common Name

Scientific Name

Spotted salamander	Ambystoma maculatum
Marbled salamander	Ambystoma opacum
Mole salamander	Ambystoma talpoideum
Small-mouthed salamander	Ambystoma texanum
Three-toed amphiuma	Amphiuma tridactylum
Dusky salamander	Desmognathus fuscus
Dwarf salamander	Eurycea quadridigitata
Eastern Newt	Notophthalmus viridescens
Lesser siren	Siren intermedia
American toad	Bufo americanus
Woodhouse's toad	Bufo woodhousei
Northern cricket frog	Acris crepitans
Cope's gray treefrog	Hyla chryoscelis
Green treefrog	Hyla cinerea
Spring peeper	Hyla crucifer
Strecker's chorus frog	Pseudacris streckeri
Striped chorus frog	Pseudacris triseriata
Eastern narrow-mouthed toad	Gastrophryne carolinensis
Eastern spadefoot	Scaphiopus holbrookii
Crawfish frog	Rana areolata
Bullfrog	Rana catesbeiana
Green frog	Rana clamitans
Pickerel frog	Rana palustris
Southern leopard frog	Rana sphenoccephala

REPTILES POSSIBLY OCCURRING WITHIN BAYOU PIERRE RIVER BASIN

<u>Common Name</u>	<u>Scientific Name</u>
Common snapping turtle	Chelydra serpentina
Alligator snapping turtle	Macrolemys temminckii
Painted turtle	Chrysemys picta
Chicken turtle	Deirochelys reticularia
Mississippi map turtle	Graptemys kohnii
False map turtle	Graptemys pseudogeographica
River cooter	Pseudemys concinna
Cooter	Pseudemys floridana
Eastern box turtle	Terrapene carolina
Ornate box turtle	Terrapene ornata
Common slider	Trachemys scripta
Eastern mud turtle	Kinosternon subrubrum
Razor-backed musk turtle	Sternotherus carolinatus
Common musk turtle	Sternotherus odoratus
Smooth softshell turtle	Apalone mutica
Spiny softshell turtle	Apalone spinifer
Slender glass lizard	Ophisaurus attenuatus
Green anole	Anolis carolinensis
Texas horned lizard	Phrynosoma cornutum
Eastern fence lizard	Sceloporus undulatus
Coal skink	Eumeces anthracinus
Five-lined skink	Eumeces fasciatus
Broad-headed skink	Eumeces laticeps
Prairie skink	Eumeces septentrionalis
Ground skink	Scincella lateralis
Six-lined racerunner	Cnemidophorus sexlineatus
Scarlet snake	Cemophora coccinea
Racer	Coluber constrictor
Ring-necked snake	Diadophis punctatus
Corn snake	Elaphe guttata
Rat snake	Elaphe obsoleta
Eastern hognose snake	Heterodon platyrhinos
Prairie kingsnake	Lampropeltis calligaster
Common kingsnake	Lampropeltis getulus
Milk snake	Lampropeltis triangulum
Coachwhip	Masticophis flagellum
Green water snake	Nerodia cyclopion
Plain-bellied water snake	Nerodia erythrogaster
Southern water snake	Nerodia fasciata
Diamondback water snake	Nerodia rhombifera
Rough green snake	Opheodrys aestivus
Graham's crayfish snake	Regina grahamii

Reptiles (cont)

Common Name

Glossy crayfish snake
Brown snake
Red-bellied snake
Flat-headed snake
Western ribbon snake
Common garter snake
Rough earth snake
Smooth earth snake
Eastern coral snake
Copperhead
Cottonmouth
Timber rattlesnake
Pigmy rattlesnake
American alligator

Scientific Name

Regina rigida
Storeria dekayi
Storeria occipitomaculata
Tantilla gracilis
Thamnophis proximus
Thamnophis sirtalis
Virginia striatula
Virginia valeriae
Micrurus fulvius
Agkistrodon contortrix
Agkistrodon piscivorus
Crotalus horridus
Sistrurus miliarius
Alligator mississippiensis

BIRDS POSSIBLY OCCURRING WITHIN BAYOU PIERRE RIVER BASIN

<u>Common Name</u>	<u>Scientific Name</u>
Red-throated Loon	<i>Gavia stellata</i>
Common Loon	<i>Gavia immer</i>
Least Grebe	<i>Tachybaptus dominicus</i>
Pied-billed Grebe	<i>Podilymbus podiceps</i>
Horned Grebe	<i>Podiceps auritus</i>
Red-necked Grebe	<i>Podiceps grisegena</i>
Eared Grebe	<i>Podiceps nigricollis</i>
Western Grebe	<i>Aechmophorus occidentalis</i>
Yellow-nosed Albatross	<i>Diomedea chlororhynchos</i>
Cory's Shearwater	<i>Calonectris diomedea</i>
Greater Shearwater	<i>Puffinus gravis</i>
Sooty Shearwater	<i>Puffinus griseus</i>
Audubon's Shearwater	<i>Puffinus lherminieri</i>
Wilson's Storm-Petrel	<i>Oceanites oceanicus</i>
Leach's Storm-Petrel	<i>Oceanodroma leucorhoa</i>
White-tailed Tropicbird	<i>Phaethon lepturus</i>
Masked Booby	<i>Sula dactylatra</i>
Brown Booby	<i>Sula leucogaster</i>
Red-footed Booby	<i>Sula sula</i>
Northern Gannet	<i>Morus bassanus</i>
American White Pelican	<i>Pelecanus erythrorhynchos</i>
Brown Pelican	<i>Pelecanus occidentalis</i>
Great Cormorant	<i>Phalacrocorax carbo</i>
Double-crested Cormorant	<i>Phalacrocorax auritus</i>
Olivaceous Cormorant	<i>Phalacrocorax olivaceus</i>
Anhinga	<i>Anhinga anhinga</i>
Magnificent Frigatebird	<i>Fregata magnificens</i>
American Bittern	<i>Botaurus lentiginosus</i>
Least Bittern	<i>Ixobrychus exilis</i>
Great Blue Heron	<i>Ardea herodias</i>
Great Egret	<i>Casmerodius albus</i>
Snowy Egret	<i>Egretta thula</i>
Little Blue Heron	<i>Egretta caerulea</i>
Tricolored Heron	<i>Egretta tricolor</i>
Reddish Egret	<i>Egretta rufescens</i>
Cattle Egret	<i>Bubulcus ibis</i>
Green-backed Heron	<i>Butorides striatus</i>
Black-crowned Night-Heron	<i>Nycticorax nycticorax</i>
Yellow-crowned Night-Heron	<i>Nyctanassa violaceus</i>
White Ibis	<i>Eudocimus albus</i>
Glossy Ibis	<i>Plegadis falcinellus</i>
White-faced Ibis	<i>Plegadis chihi</i>

Birds (cont)

Common Name

Roseate Spoonbill
Wood Stork
Fulvous Whistling-Duck
Black-bellied Whistling-Duck
Tundra Swan
Trumpeter Swan
Greater White-fronted Goose
Snow Goose
Ross' Goose
Brant
Canada Goose
Wood Duck
Green-winged Teal
American Black Duck
Mottled Duck
Mallard
Northern Pintail
Blue-winged Teal
Cinnamon Teal
Northern Shoveler
Gadwall
Eurasian Wigeon
American Wigeon
Canvasback
Redhead
Ring-necked Duck
Greater Scaup
Lesser Scaup
Harlequin Duck
Oldsquaw
Black Scoter
Surf Scoter
White-winged Scoter
Common Goldeneye
Bufflehead
Hooded Merganser
Common Merganser
Red-breasted Merganser
Ruddy Duck
Masked Duck
Black Vulture
Turkey Vulture

Scientific Name

Ajaia ajaja
Mycteria americana
Dendrocygna bicolor
Dendrocygna autumnalis
Cygnus columbianus
Cygnus buccinator
Anser albifrons
Chen caerulescens
Chen rossii
Branta bernicla
Branta canadensis
Aix sponsa
Anas crecca
Anas rubripes
Anas fulvigula
Anas platyrhynchos
Anas acuta
Anas discors
Anas cyanoptera
Anas clypeata
Anas strepera
Anas penelope
Anas americana
Aythya valisineria
Aythya americana
Aythya collaris
Aythya marila
Aythya affinis
Histrionicus histrionicus
Clangula hyemalis
Melanitta nigra
Melanitta perspicillata
Melanitta fusca
Bucephala clangula
Bucephala albeola
Lophodytes cucullatus
Mergus merganser
Mergus serrator
Oxyura jamaicensis
Oxyura dominica
Coragyps atratus
Cathartes aura

Birds (continued)

Common Name

Scientific Name

Osprey
American Swallow-tailed Kite
Black-shouldered Kite
Mississippi Kite
Bald Eagle
Northern Harrier
Sharp-shinned Hawk
Cooper's Hawk
Northern Goshawk
Harris' Hawk
Red-shouldered Hawk
Broad-winged Hawk
Swainson's Hawk
White-tailed Hawk
Red-tailed Hawk
Ferruginous Hawk
Rough-legged Hawk
Golden Eagle
Crested Caracara
American Kestrel
Merlin
Peregrine Falcon
Prairie Falcon
Black Francolin
Ring-necked Pheasant
Greater Prairie-Chicken
Wild Turkey
Northern Bobwhite
Yellow Rail
Black Rail
Clapper Rail
King Rail
Virginia Rail
Sora
Purple Gallinule
Common Moorhen
American Coot
Sandhill Crane
Whooping Crane
Black-bellied Plover
Lesser Golden-Plover
Mongolian Plover

Pandion haliaetus
Elanoides forficatus
Elanus caeruleus
Ictinia mississippiensis
Haliaetus leucocephalus
Circus cyaneus
Accipiter striatus
Accipiter cooperii
Accipiter gentilis
Parabuteo unicinctus
Buteo lineatus
Buteo platypterus
Buteo swainsoni
Buteo albicaudatus
Buteo jamaicensis
Buteo regalis
Buteo lagopus
Aquila chrysaetos
Polyborus plancus
Falco sparverius
Falco columbarius
Falco peregrinus
Falco mexicanus
Francolinus francolinus
Phasianus colchicus
Tympanuchus cupido
Meleagris gallopavo
Colinus virginianus
Coturnicops noveboracensis
Laterallus jamaicensis
Rallus longirostris
Rallus elegans
Rallus limicola
Porzana carolina
Porphyrula martinica
Gallinula chloropus
Fulica americana
Grus canadensis
Grus americana
Pluvialis squatarola
Pluvialis dominica
Charadrius mongolus

Birds (continued)

Common Name

Snowy Plover
Wilson's Plover
Semipalmated Plover
Piping Plover
Killdeer
American Oystercatcher
Black-necked Stilt
American Avocet
Greater Yellowlegs
Lesser Yellowlegs
Solitary Sandpiper
Willet
Spotted Sandpiper
Upland Sandpiper
Eskimo Curlew
Whimbrel
Long-billed Curlew
Hudsonian Godwit
Marbled Godwit
Ruddy Turnstone
Red Knot
Sanderling
Semipalmated Sandpiper
Western Sandpiper
Least Sandpiper
White-rumped Sandpiper
Baird's Sandpiper
Pectoral Sandpiper
Purple Sandpiper
Dunlin
Curlew Sandpiper
Stilt Sandpiper
Buff-breasted Sandpiper
Ruff
Short-billed Dowitcher
Long-billed Dowitcher
Common Snipe
American Woodcock
Wilson's Phalarope
Red-necked Phalarope
Red Phalarope
Pomarine Jaeger

Scientific Name

Charadrius alexandrinus
Charadrius wilsonia
Charadrius semipalmatus
Charadrius melodus
Charadrius vociferus
Haematopus palliatus
Himantopus mexicanus
Recurvirostra americana
Tringa melanoleuca
Tringa flavipes
Tringa solitaria
Catoptrophorus semipalmatus
Actitis macularia
Bartramia longicauda
Numenius borealis
Numenius phaeopus
Numenius americanus
Limosa haemastica
Limosa fedoa
Arenaria interpres
Calidris canutus
Calidris alba
Calidris pusilla
Calidris mauri
Calidris minutilla
Calidris fuscicollis
Calidris bairdii
Calidris melanotos
Calidris maritima
Calidris alpina
Calidris ferruginea
Calidris himantopus
Tryngites subruficollis
Philomachus pugnax
Limnodromus griseus
Limnodromus scolopaceus
Gallinago gallinago
Scolopax minor
Phalaropus tricolor
Phalaropus lobatus
Phalaropus fulicarius
Stercorarius pomarinus

Birds (continued)

Common Name

Scientific Name

Parasitic Jaeger
Long-tailed Jaeger
Great Skua
Laughing Gull
Franklin's Gull
Little Gull
Bonaparte's Gull
Ring-billed Gull
Herring Gull
Thayer's Gull
Lesser Black-backed Gull
Glaucous Gull
Great Black-backed Gull
Black-legged Kittiwake
Sabine's Gull
Gull-billed Tern
Caspian Tern
Royal Tern
Sandwich Tern
Roseate Tern
Common Tern
Forster's Tern
Least Tern
Bridled Tern
Sooty Tern
Black Tern
Brown Noddy
Black Skimmer
Ancient Murrelet
Rock Dove
Band-tailed Pigeon
White-winged Dove
Mourning Dove
Inca Dove
Common Ground-Dove
Monk Parakeet
Black-billed Cuckoo
Yellow-billed Cuckoo
Greater Roadrunner
Smooth-billed Ani
Groove-billed Ani
Barn-Owl

Stercorarius parasiticus
Stercorarius longicaudus
Catharacta skua
Larus atricilla
Larus pipixcan
Larus minutus
Larus philadelphia
Larus delawarensis
Larus argentatus
Larus thayeri
Larus fuscus
Larus hyperboreus
Larus marinus
Rissa tridactyla
Xema sabini
Sterna nilotica
Sterna caspia
Sterna maxima
Sterna sandvicensis
Sterna dougallii
Sterna hirundo
Sterna forsteri
Sterna antillarum
Sterna anaethetus
Sterna fuscata
Chlidonias niger
Anous stolidus
Rynchops niger
Synthliboramphus antiquus
Columba livia
Columba fasciata
Zenaida asiatica
Zenaida macroura
Columbina inca
Columbia passerina
Myiopsitta monachus
Coccyzus erythrophthalmus
Coccyzus americanus
Geococcyx californianus
Crotophaga ani
Crotophaga sulcirostris
Tyto alba

Birds (continued)

Common Name

Flammulated Owl
Eastern Screech-Owl
Great Horned Owl
Snowy Owl
Burrowing Owl
Barred Owl
Long-eared Owl
Short-eared Owl
Northern Saw-whet Owl
Lesser Nighthawk
Common Nighthawk
Antillean Nighthawk
Chuck-will's-willow
Whip-poor-will
Chimney Swift
Vaux's Swift
Buff-bellied Hummingbird
Ruby-throated Hummingbird
Black-chinned Hummingbird
Anna's Hummingbird
Calliope Hummingbird
Broad-tailed Hummingbird
Rufous Hummingbird
Allen's Hummingbird
Belted Kingfisher
Red-headed Woodpecker
Red-bellied Woodpecker
Yellow-bellied Sapsucker
Williamson's Sapsucker
Downy Woodpecker
Hairy Woodpecker
Red-cockaded Woodpecker
Northern Flicker
Pileated Woodpecker
Olive-sided Flycatcher
Western Wood-Pewee
Eastern Wood-Pewee
Yellow-bellied Flycatcher
Acadian Flycatcher
Alder Flycatcher
Willow Flycatcher
Least Flycatcher

Scientific Name

Otus flammeolus
Otus asio
Bubo virginianus
Nyctea scandiaca
Athene cunicularia
Strix varia
Asio otus
Asio flammeus
Aegolius acadicus
Chordeiles acutipennis
Chordeiles minor
Chordeiles gundlachii
Caprimulgus carolinensis
Caprimulgus vociferus
Chaetura pelagica
Chaetura vauxi
Amazilia yucatanensis
Archilochus colubris
Archilochus alexandri
Calypte anna
Stellula calliope
Selasphorus platycercus
Selasphorus rufus
Selasphorus sasin
Ceryle alcyon
Melanerpes erythrocephalus
Melanerpes carolinus
Sphyrapicus varius
Sphyrapicus thyroideus
Picoides pubescens
Picoides villosus
Picoides borealis
Colaptes auratus
Dryocopus pileatus
Contopus borealis
Contopus sordidulus
Contopus virens
Empidonax flaviventris
Empidonax virescens
Empidonax alnorum
Empidonax traillii
Empidonax minimus

Birds (continued)

Common Name

Hammond's Flycatcher
Eastern Phoebe
Say's Phoebe
Vermilion Flycatcher
Ash-throated Flycatcher
Great Crested Flycatcher
Brown-crested Flycatcher
Great Kiskadee
Sulphur-bellied Flycatcher
Couch's Kingbird
Tropical Kingbird
Cassin's Kingbird
Western Kingbird
Eastern Kingbird
Gray Kingbird
Scissor-tailed Flycatcher
Horned Lark
Purple Martin
Tree Swallow
Northern Rough-winged Swallow
Bank Swallow
Cliff Swallow
Barn Swallow
Blue Jay
American Crow
Fish Crow
Carolina Chickadee
Tufted Titmouse
Red-breasted Nuthatch
White-breasted Nuthatch
Brown-headed Nuthatch
Brown Creeper
Rock Wren
Carolina Wren
Bewick's Wren
House Wren
Winter Wren
Sedge Wren
Marsh Wren
Golden-crowned Kinglet
Ruby-crowned Kinglet
Blue-gray Gnatcatcher

Scientific Name

Empidonax hammondii
Sayornis phoebe
Sayornis saya
Pyrocephalus rubinus
Myiarchus cinerascens
Myiarchus crinitus
Myiarchus tyrannulus
Pitangus sulphuratus
Myiodynastes luteiventris
Tyrannus couchii
Tyrannus melancholicus
Tyrannus vociferans
Tyrannus verticalis
Tyrannus tyrannus
Tyrannus dominicensis
Tyrannus forficatus
Eremophila alpestris
Progne subis
Tachycineta bicolor
Stelgidopteryx serripennis
Riparia riparia
Hirundo pyrrhonota
Hirundo rustica
Cyanocitta cristata
Corvus brachyrhynchos
Corvus ossifragus
Parus carolinensis
Parus bicolor
Sitta canadensis
Sitta carolinensis
Sitta pusilla
Certhia americana
Salpinctes obsoletus
Thryothorus ludovicianus
Thryomanes bewickii
Troglodytes aedon
Troglodytes troglodytes
Cistothorus platensis
Cistothorus palustris
Regulus satrapa
Regulus calendula
Polioptila caerulea

Birds (continued)

Common Name

Scientific Name

Northern Wheatear
Eastern Bluebird
Mountain Bluebird
Veery
Gray-cheeked Thrush
Swainson's Thrush
Hermit Thrush
Wood Thrush
American Robin
Gray Catbird
Northern Mockingbird
Sage Thrasher
Brown Thrasher
Curve-billed Thrasher
American Pipit
Sprague's Pipit
Cedar Waxwing
Loggerhead Shrike
European Starling
White-eyed Vireo
Bell's Vireo
Solitary Vireo
Yellow-throated Vireo
Warbling Vireo
Philadelphia Vireo
Red-eyed Vireo
Black-whiskered Vireo
Bachman's Warbler
Blue-winged Warbler
Golden-winged Warbler
Tennessee Warbler
Orange-crowned Warbler
Nashville Warbler
Lucy's Warbler
Northern Parula
Tropical Parula
Yellow Warbler
Chestnut-sided Warbler
Magnolia Warbler
Cape May Warbler
Black-throated Blue Warbler

Oenanthe oenanthe
Sialia sialis
Sialia currucoides
Catharus fuscescens
Catharus minimus
Catharus ustulatus
Catharus guttatus
Hylocichla mustelina
Turdus migratorius
Dumetella carolinensis
Mimus polyglottos
Oreoscoptes montanus
Toxostoma rufum
Toxostoma curvirostre
Anthus spinoletta
Anthus spragueii
Bombycilla cedrorum
Lanius ludovicianus
Sturnus vulgaris
Vireo griseus
Vireo bellii
Vireo solitarius
Vireo flavifrons
Vireo gilvus
Vireo philadelphicus
Vireo olivaceus
Vireo altiloquus
Vermivora bachmanii
Vermivora pinus
Vermivora chrysoptera
Vermivora peregrina
Vermivora celata
Vermivora ruficapilla
Vermivora luciae
Parula americana
Parula pitiayumi
Dendroica petechia
Dendroica pensylvanica
Dendroica magnolia
Dendroica tigrina
Dendroica caerulescens

Birds (continued)

Common Name

Yellow-rumped Warbler
Black-throated Gray Warbler
Townsend's Warbler
Hermit Warbler
Black-throated Green Warbler
Blackburnian Warbler
Yellow-throated Warbler
Pine Warbler
Prairie Warbler
Palm Warbler
Bay-breasted Warbler
Blackpoll Warbler
Cerulean Warbler
Black-and-white Warbler
American Redstart
Prothonotary Warbler
Worm-eating Warbler
Swainson's Warbler
Ovenbird
Northern Waterthrush
Louisiana Waterthrush
Kentucky Warbler
Connecticut Warbler
Mourning Warbler
MacGillivray's Warbler
Common Yellowthroat
Hooded Warbler
Wilson's Warbler
Canada Warbler
Painted Redstart
Yellow-breasted Chat
Hepatic Tanager
Summer Tanager
Scarlet Tanager
Western Tanager
Northern Cardinal
Rose-breasted Grosbeak
Black-headed Grosbeak
Blue Bunting
Blue Grosbeak
Indigo Bunting

Scientific Name

Dendroica coronata
Dendroica nigrescens
Dendroica townsendi
Dendroica occidentalis
Dendroica virens
Dendroica fusca
Dendroica dominica
Dendroica pinus
Dendroica discolor
Dendroica palmarum
Dendroica castanea
Dendroica striata
Dendroica cerulea
Mniotilta varia
Setophaga ruticilla
Protonotaria citrea
Helmitheros vermivorus
Limnothlypis swainsonii
Seiurus aurocapillus
Seiurus noveboracensis
Seiurus motacilla
Oporornis formosus
Oporornis agilis
Oporornis philadelphia
Oporornis tolmiei
Geothlypis trichas
Wilsonia citrina
Wilsonia pusilla
Wilsonia canadensis
Myioborus pictus
Icteria virens
Piranga flava
Piranga rubra
Piranga olivacea
Piranga ludoviciana
Cardinalis cardinalis
Pheucticus ludovicianus
Pheucticus melanocephalus
Cyanocompsa parellina
Guiraca caerulea
Passerina cyanea

Birds (continued)

Common Name

Painted Bunting
Dickcissel
Green-tailed Towhee
Rufous-sided Towhee
Bachman's Sparrow
American Tree Sparrow
Chipping Sparrow
Clay-colored Sparrow
Brewer's Sparrow
Field Sparrow
Vesper Sparrow
Lark Sparrow
Black-throated Sparrow
Lark Bunting
Savannah Sparrow
Grasshopper Sparrow
Henslow's Sparrow
LeConte's Sparrow
Sharp-tailed Sparrow
Seaside Sparrow
Fox Sparrow
Song Sparrow
Lincoln's Sparrow
Swamp Sparrow
White-throated Sparrow
Golden-crowned Sparrow
White-crowned Sparrow
Harris' Sparrow
Dark-eyed Junco
McCown's Longspur
Lapland Longspur
Smith's Longspur
Chestnut-collared Longspur
Snow Bunting
Bobolink
Red-winged Blackbird
Eastern Meadowlark
Western Meadowlark
Yellow-headed Blackbird
Rusty Blackbird
Brewer's Blackbird
Great-tailed Grackle

Scientific Name

Passerina ciris
Spiza americana
Pipilo chlorurus
Pipilo erythrophthalmus
Aimophila aestivalis
Spizella arborea
Spizella passerina
Spizella pallida
Spizella breweri
Spizella pusilla
Pooecetes gramineus
Chondestes grammacus
Amphispiza bilineata
Calamospiza melanocorys
Passerculus sandwichensis
Ammodramus savannarum
Ammodramus henslowii
Ammodramus leconteii
Ammodramus caudacutus
Ammodramus maritimus
Passerella iliaca
Melospiza melodia
Melospiza lincolnii
Melospiza georgiana
Zonotrichia albicollis
Zonotrichia atricapilla
Zonotrichia leucophrys
Zonotrichia querula
Junco hyemalis
Calcarius mccownii
Calcarius lapponicus
Calcarius pictus
Calcarius ornatus
Plectrophenax nivalis
Dolichonyx oryzivorus
Agelaius phoeniceus
Sturnella magna
Sturnella neglecta
Xanthocephalus xanthocephalus
Euphagus carolinus
Euphagus cyanocephalus
Quiscalus mexicanus

Birds (continued)

Common Name

Boat-tailed Grackle
Common Grackle
Bronzed Cowbird
Brown-headed Cowbird
Orchard Oriole
Northern Oriole
Scott's Oriole
Purple Finch
House Finch
Red Crossbill
Common Redpoll
Pine Siskin
Lesser Goldfinch
American Goldfinch
Evening Grosbeak
House Sparrow

Scientific Name

Quiscalus major
Quiscalus quisqualis
Molothrus aeneus
Molothrus ater
Icterus spurius
Icterus galbula
Icterus parisorum
Carpodacus purpureus
Carpodacus mexicanus
Loxia curvirostra
Carduelis flammea
Carduelis pinus
Carduelis psaltria
Carduelis tristis
Coccothraustes vespertinus
Passer domesticus

MAMMALS POSSIBLY OCCURRING WITHIN BAYOU PIERRE RIVER BASIN

<u>Common Name</u>	<u>Scientific Name</u>
Virginia opossum	<i>Didelphis virginiana</i>
Short-tailed shrew	<i>Blarina brevicauda</i>
Least shrew	<i>Cryptotis parva</i>
Eastern mole	<i>Scalopus aquaticus</i>
Southeastern myotis	<i>Myotis austroriparius</i>
Eastern pipistrelle	<i>Pipistrellus subflavus</i>
Big brown bat	<i>Eptesicus fuscus</i>
Red bat	<i>Lasiurus borealis</i>
Seminole bat	<i>Lasiurus seminolus</i>
Hoary bat	<i>Lasiurus cinereus</i>
Evening bat	<i>Nycticeius humeralis</i>
Rafinesque's big-eared bat	<i>Plecotus rafinesquii</i>
Brazilian free-tailed bat	<i>Tadarida brasiliensis</i>
Nine-banded armadillo	<i>Dasypus novemcinctus</i>
Eastern cottontail	<i>Sylvilagus floridanus</i>
Swamp rabbit	<i>Sylvilagus aquaticus</i>
Gray squirrel	<i>Sciurus carolinensis</i>
Fox squirrel	<i>Sciurus niger</i>
Woodchuck	<i>Marmota monax</i>
Southern flying squirrel	<i>Glaucomys volans</i>
Plains pocket gopher	<i>Geomys bursarius</i>
American beaver	<i>Castor canadensis</i>
Marsh rice rat	<i>Oryzomys palustris</i>
Eastern harvest mouse	<i>Reithrodontomys humulilis</i>
Fulvous harvest mouse	<i>Reithrodontomys fulvescens</i>
White-footed mouse	<i>Peromyscus leucopus</i>
Cotton mouse	<i>Peromyscus gossypinus</i>
Golden mouse	<i>Ochrotomys nuttalli</i>
Hispid cotton rat	<i>Sigmodon hispidus</i>
Eastern wood rat	<i>Neotoma floridana</i>
Woodland vole	<i>Microtus pinetorum</i>
Common muskrat	<i>Ondatra zibethicus</i>
Roof rat	<i>Rattus rattus</i>
Norway rat	<i>Rattus norvegicus</i>
House mouse	<i>Mus musculus</i>
Nutria	<i>Myocaster coypus</i>
Coyote	<i>Canis latrans</i>
Red wolf	<i>Canis rufus</i>
Red fox	<i>Vulpes vulpes</i>
Gray fox	<i>Urocyon cinereoargenteus</i>
American black bear	<i>Euarctos americanus</i>
Ringtail	<i>Bassariscus astutus</i>

Mammals (continued)

Common Name

Northern raccoon
Long-tailed weasel
North American Mink
Striped skunk
Nearctic river otter
Cougar
Bobcat
White-tailed deer

Scientific Name

Procyon lotor
Mustela frenata
Mustela vison
Mephitis mephitis
Lutra canadensis
Felis concolor
Lynx felis
Odocoileus virginianus

FIELD CHECKLIST of the BIRDS of the BAYOU PIERRE COOPERATIVE RIVER BASIN

Compiled by James L. Ingold, Ph.D.

Based on records in the observation database compiled by the Bird Study Group

Shreveport Society for Nature Study, Inc.

Website: <http://www.softdisk.com/comp/birds/index.html>

GREBES

- ___ Pied-billed Grebe
- ___ Horned Grebe
- ___ Eared Grebe

PELICANS

- ___ American White Pelican

CORMORANTS, DARTERS

- ___ Neotropic Cormorant
- ___ Double-crested Cormorant
- ___ Anhinga

BITTERNS, HERONS, etc.

- ___ American Bittern
- ___ Least Bittern
- ___ Great Blue Heron
- ___ Great Egret
- ___ Snowy Egret
- ___ Little Blue Heron
- ___ Tricolored Heron
- ___ Cattle Egret
- ___ Green Heron
- ___ Black-crowned Night-Heron
- ___ Yellow-crowned Night-Heron

IBISES, SPOONBILLS

- ___ White Ibis
- ___ White-faced Ibis
- ___ Roseate Spoonbill

STORKS

- ___ Wood Stork

NEW WORLD VULTURES

- ___ Black Vulture
- ___ Turkey Vulture

GEESE, DUCKS

- ___ Black-bellied Whistling-Duck
- ___ Fulvous Whistling-Duck
- ___ Gr. White-fronted Goose
- ___ Snow Goose
- ___ Ross' Goose
- ___ Tundra Swan
- ___ Wood Duck
- ___ Gadwall
- ___ American Wigeon
- ___ Mallard
- ___ Blue-winged Teal
- ___ Cinnamon Teal
- ___ Northern Shoveler
- ___ Northern Pintail
- ___ Green-winged Teal
- ___ Canvasback
- ___ Redhead
- ___ Ring-necked Duck
- ___ Greater Scaup
- ___ Lesser Scaup
- ___ Surf Scoter
- ___ Black Scoter
- ___ Bufflehead
- ___ Hooded Merganser
- ___ Common Merganser
- ___ Red-breasted Merganser
- ___ Ruddy Duck

KITES, EAGLES

- ___ Osprey
- ___ Swallow-tailed Kite
- ___ White-tailed Kite
- ___ Mississippi Kite
- ___ Bald Eagle

HAWKS

- ___ Northern Harrier
- ___ Sharp-shinned Hawk
- ___ Cooper's Hawk
- ___ Red-shouldered Hawk
- ___ Broad-winged Hawk
- ___ Swainson's Hawk
- ___ Red-tailed Hawk
- ___ Rough-legged Hawk
- ___ Golden Eagle

FALCONS

- ___ American Kestrel
- ___ Merlin
- ___ Peregrine Falcon

TURKEYS, QUAIL

- ___ Wild Turkey
- ___ Northern Bobwhite

RAILS, COOTS

- ___ Yellow Rail
- ___ Black Rail
- ___ King Rail
- ___ Virginia Rail
- ___ Sora
- ___ Purple Gallinule
- ___ Common Moorhen
- ___ American Coot

CRANES

- ___ Sandhill Crane

PLOVERS

- ___ Black-bellied Plover
- ___ American Golden-Plover
- ___ Snowy Plover
- ___ Semipalmated Plover
- ___ Piping Plover
- ___ Killdeer

STILTS, AVOCETS

- ___ Black-necked Stilt
- ___ American Avocet

SANDPIPERS

- ___ Greater Yellowlegs
- ___ Lesser Yellowlegs
- ___ Solitary Sandpiper
- ___ Willet
- ___ Spotted Sandpiper
- ___ Upland Sandpiper
- ___ Long-billed Curlew
- ___ Hudsonian Godwit
- ___ Ruddy Turnstone
- ___ Red Knot
- ___ Sanderling
- ___ Semipalmated Sandpiper
- ___ Western Sandpiper
- ___ Least Sandpiper

- ___ White-rumped Sandpiper
- ___ Baird's Sandpiper
- ___ Pectoral Sandpiper
- ___ Dunlin
- ___ Stilt Sandpiper
- ___ Buff-breasted Sandpiper
- ___ Short-billed Dowitcher
- ___ Long-billed Dowitcher
- ___ Common Snipe
- ___ American Woodcock
- ___ Wilson's Phalarope

GULLS, TERNS

- ___ Laughing Gull
- ___ Franklin's Gull
- ___ Bonaparte's Gull
- ___ Ring-billed Gull
- ___ Herring Gull
- ___ Sabine's Gull
- ___ Caspian Tern
- ___ Common Tern
- ___ Forster's Tern
- ___ Least Tern
- ___ Sooty Tern
- ___ Black Tern

PIGEONS, DOVES

- ___ Rock Dove
- ___ Band-tailed Pigeon
- ___ Eurasian Collared-Dove
- ___ White-winged Dove
- ___ Mourning Dove
- ___ Inca Dove
- ___ Common Ground-Dove

CUCKOOS

- ___ Black-billed Cuckoo
- ___ Yellow-billed Cuckoo
- ___ Greater Roadrunner

OWLS

- ___ Barn Owl
- ___ Eastern Screech-Owl
- ___ Great Horned Owl
- ___ Barred Owl
- ___ Long-eared Owl
- ___ Short-Eared Owl

GOATSUCKERS

- ___ Common Nighthawk
- ___ Chuck-will's widow
- ___ Whip-poor-will

SWIFTS

- ___ Chimney Swift

HUMMINGBIRDS

- ___ Ruby-throated Hummingbird
- ___ Rufous Hummingbird

KINGFISHERS

- ___ Ringed Kingfisher
- ___ Belted Kingfisher

WOODPECKERS

___ Red-headed Woodpecker
___ Red-bellied Woodpecker
___ Yellow-bellied Sapsucker
___ Downy Woodpecker
___ Hairy Woodpecker
___ Northern Flicker
___ Pileated Woodpecker

TYRANT FLYCATCHERS

___ Olive-sided Flycatcher
___ Eastern Wood-Pewee
___ Yellow-bellied Flycatcher
___ Acadian Flycatcher
___ Alder Flycatcher
___ Willow Flycatcher
___ Least Flycatcher
___ Eastern Phoebe
___ Vermilion Flycatcher
___ Great Crested Flycatcher
___ Western Kingbird
___ Eastern Kingbird
___ Scissor-tailed Flycatcher

SHRIKES

___ Loggerhead Shrike

VIREOS

___ White-eyed Vireo
___ Bell's Vireo
___ Yellow-throated Vireo
___ Blue-headed Vireo
___ Warbling Vireo
___ Philadelphia Vireo
___ Red-eyed Vireo

JAYS, CROWS

___ Blue Jay
___ American Crow
___ Fish Crow

LARKS

___ Horned Lark

SWALLOWS

___ Purple Martin
___ Tree Swallow
___ No. Rough-winged Swallow
___ Bank Swallow
___ Cliff Swallow
___ Barn Swallow

CHICKADEES, TITMICE

___ Carolina Chickadee
___ Tufted Titmouse

NUTHATCHES

___ Red-breasted Nuthatch
___ White-breasted Nuthatch
___ Brown-headed Nuthatch

CREEPERS

___ Brown Creeper

WRENS

___ Carolina Wren
___ Bewick's Wren
___ House Wren
___ Winter Wren
___ Sedge Wren
___ Marsh Wren

MUSCICAPIDS

___ Golden-crowned Kinglet
___ Ruby-crowned Kinglet
___ Blue-gray Gnatcatcher
___ Northern Wheatear
___ Eastern Bluebird
___ Veery
___ Gray-cheeked Thrush

___ Swainson's Thrush
___ Hermit Thrush
___ Wood Thrush
___ American Robin

MOCKINGBIRDS

___ Gray Catbird
___ Northern Mockingbird
___ Brown Thrasher

STARLINGS

___ European Starling

PIPITS

___ American Pipit
___ Sprague's Pipit

WAXWINGS

___ Cedar Waxwing

WARBLERS

___ Blue-winged Warbler
___ Golden-winged Warbler
___ Tennessee Warbler
___ Orange-crowned Warbler
___ Nashville Warbler
___ Northern Parula
___ Tropical Parula
___ Yellow Warbler
___ Chestnut-sided Warbler
___ Magnolia Warbler
___ Black-throated Blue Warbler
___ Yellow-rumped Warbler
___ Black-th. Green Warbler
___ Blackburnian Warbler
___ Yellow-throated Warbler
___ Pine Warbler
___ Prairie Warbler
___ Palm Warbler
___ Bay-breasted Warbler
___ Blackpoll Warbler
___ Cerulean Warbler
___ Black-and-white Warbler
___ American Redstart
___ Prothonotary Warbler
___ Worm-eating Warbler
___ Swainson's Warbler
___ Ovenbird
___ Northern Waterthrush
___ Louisiana Waterthrush
___ Kentucky Warbler
___ Connecticut Warbler
___ Mourning Warbler
___ Common Yellowthroat
___ Hooded Warbler
___ Wilson's Warbler
___ Canada Warbler
___ Yellow-breasted Chat

TANAGERS

___ Summer Tanager
___ Scarlet Tanager

SPARROWS

___ Spotted Towhee
___ Eastern Towhee
___ Chipping Sparrow
___ Clay-colored Sparrow
___ Field Sparrow
___ Vesper Sparrow
___ Lark Sparrow
___ Savannah Sparrow
___ Grasshopper Sparrow
___ Henslow's Sparrow
___ LeConte's Sparrow
___ Nelson's Sharp-tailed Sparrow

___ Fox Sparrow
___ Song Sparrow
___ Lincoln's Sparrow
___ Swamp Sparrow
___ White-throated Sparrow
___ Harris' Sparrow
___ White-crowned Sparrow
___ Dark-eyed Junco
___ Lapland Longspur

CARDINALS, etc.

___ Northern Cardinal
___ Rose-breasted Grosbeak
___ Blue Grosbeak
___ Indigo Bunting
___ Painted Bunting
___ Dickcissel

ICTERIDS

___ Bobolink
___ Red-winged Blackbird
___ Eastern Meadowlark
___ Western Meadowlark
___ Yellow-headed Blackbird
___ Rusty Blackbird
___ Brewer's Blackbird
___ Common Grackle
___ Great-tailed Grackle
___ Brown-headed Cowbird
___ Orchard Oriole
___ Baltimore Oriole

FINCHES

___ Purple Finch
___ House Finch
___ Pine Siskin
___ Lesser Goldfinch
___ American Goldfinch
___ Evening Grosbeak

WEAVER FINCHES

___ House Sparrow

BAYOU PIERRE PLANT LIST (ULM Herbarium)

Order Equisetales

Family Equisetaceae – Horsetail family

Symbol Scientific Name

EQHYA Equisetum hyemale L. var. affine (Engelm.) A.A. Eat.

Common Name

scouringrush horsetail

Order Isotales

Family Isoetaceae – Quillwort family

Symbol Scientific Name

ISME Isoetes melanopoda Gay & Durieu ex Durieu

Common Name

blackfoot quillwort

Order Lycopodiales

Family Lycopodiaceae – Clubmoss family

Symbol Scientific Name

LYAL5 Lycopodiella alopecuroides (L.) Cranfill

LYAP4 Lycopodiella appressa (Chapman) Cranfill

LYCA5 Lycopodiella caroliniana (L.) Pichi Sermolli

LYCE2 Lycopodiella cernua (L.) Pichi Sermolli

LYPR3 Lycopodiella prostrata (Harper) Cranfill

Common Name

foxtail clubmoss

southern bog clubmoss

slender clubmoss

staghorn clubmoss

featherstem clubmoss

Order Selaginellales

Family Selaginellaceae – Spikemoss family

Symbol Scientific Name

SEAP Selaginella apoda (L.) Spring

SEAR Selaginella arenicola Underwood

Common Name

meadow spikemoss

sand spikemoss

Order Hydropteridales

Family Azollaceae – Azolla family

Symbol Scientific Name

AZCA Azolla caroliniana Willd.

Common Name

Carolina mosquitofern

Order Ophioglossales

Family Ophioglossaceae – Adderstongue family

Symbol Scientific Name

BOB1 Botrychium biternatum (Sav.) Underwood

BODI2 Botrychium dissectum Spreng.

BOLU2 Botrychium lunarioides (Michx.) Sw.

BOVI Botrychium virginianum (L.) Sw.

OPCR Ophioglossum crotalophoroides Walt.

OPEN Ophioglossum engelmannii Prantl

OPNU Ophioglossum nudicaule L. f.

OPPE2 Ophioglossum petiolatum Hook.

OPVU Ophioglossum vulgatum L.

Common Name

sparselobe grapefern

cutleaf grapefern

winter grapefern

rattlesnake fern

bulbous adderstongue

limestone adderstongue

least adderstongue

longstem adderstongue

southern adderstongue

BAYOU PIERRE PLANT LIST (ULM Herbarium)

Order Polypodiales

Family Aspleniaceae – Spleenwort family

<u>Symbol</u>	<u>Scientific Name</u>	<u>Common Name</u>
ASPL	<u>Asplenium platyneuron (L.) B.S.P.</u>	ebony spleenwort

Family Blechnaceae – Chainfern family

<u>Symbol</u>	<u>Scientific Name</u>	<u>Common Name</u>
WOAR	<u>Woodwardia areolata (L.) T. Moore</u>	netted chainfern
WOVI	<u>Woodwardia virginica (L.) Sm.</u>	Virginia chainfern

MOCA Modiola caroliniana (L.) G. Don
 SIRH Sida rhombifolia L.
 SISP Sida spinosa L.

Carolina bristlemallow
 cuban jute
 prickly fanpetals

Family Sterculiaceae – Cacao family

Symbol Scientific Name
 FISI2 Firmiana simplex (L.) W. Wight
 MECO4 Melochia corchorifolia L.

Common Name
 Chinese parasoltree
 chocolateweed

Family Tiliaceae – Linden family

Symbol Scientific Name
 TIAM Tilia americana L.

Common Name
 American basswood

Order Nepenthes

Family Droseraceae – Sundew family

Symbol Scientific Name
 DRBR3 Drosera brevifolia Pursh
 DRCA2 Drosera capillaris Poir.

Common Name
 sundew
 pink sundew

Family Sarraceniaceae – Pitcherplant family

Symbol Scientific Name
 SAAL4 Sarracenia alata Wood
 SAPS2 Sarracenia psittacina Michx.

Common Name
 yellow trumpets
 parrot pitcherplant

Order Primulales

Family Primulaceae – Primrose family

Symbol Scientific Name
 ANAR Anagallis arvensis L.
 ANMI4 Anagallis minima (L.) Krause
 DOME Dodecatheon meadia L.
 HOIN Hottonia inflata Ell.
 LYLA Lysimachia lanceolata Walt.
 LYRA3 Lysimachia radicans Hook.
 SAVA3 Samolus valerandi L.

Common Name
 scarlet pimpernel
 chaffweed
 pride of Ohio
 American featherfoil
 lanceleaf loosestrife
 trailing yellow loosestrife
 seaside brookweed

Order Salicales

Family Salicaceae – Willow family

Symbol Scientific Name
 POAL7 Populus alba L.
 PODE3 Populus deltoides Bartr. ex Marsh.
 SAHU2 Salix humilis Marsh.
 SANI Salix nigra Marsh.
 SASE10 Salix xsepulcralis Simonkai [alba x babylonica]

Common Name
 white poplar
 eastern cottonwood
 prairie willow
 black willow
 weeping willow

Order Theales

Family Clusiaceae – Mangosteen family

Symbol Scientific Name
 HYCR3 Hypericum crux-andreae (L.) Crantz
 HYDE Hypericum densiflorum Pursh
 HYDR Hypericum drummondii (Grev. & Hook.) Torr. & Gray
 HYFA Hypericum fasciculatum Lam.

Common Name
 St. Peterswort
 bushy St. Johnswort
 nits and lice
 peelbark St. Johnswort

HYFR	<u>Hypericum frondosum Michx.</u>	cedarglade St. Johnswort

Family Staphyleaceae – Bladdernut family

<u>Symbol</u>	<u>Scientific Name</u>	<u>Common Name</u>
STTR	<u>Staphylea trifolia L.</u>	American bladdernut

Family Zygophyllaceae – Creosote-bush family

<u>Symbol</u>	<u>Scientific Name</u>	<u>Common Name</u>
TRTE	<u>Tribulus terrestris L.</u>	puncturevine

APPENDIX C. Funding Sources.

Funding Sources (organized according to topic)

Agriculture

U.S. Department of Agriculture

Conservation Reserve Program (FSA)

Environmental Quality Incentive Program (NRCS)

Disaster Prevention and Relief

Federal Emergency Management Agency

Flood Mitigation Assistance Program

Hazard Mitigation Grant Program

Project Impact Grant Program

U.S. Department of Agriculture

Emergency Conservation Program (FSA)

U.S. Environmental Protection Agency

Superfund Technical Assistance Grants for Citizen Groups at Priority Site (OERR)

Economic Development

U.S. Department of Agriculture

Water and Waste Disposal Systems for Rural Communities (RUS)

U.S. Department of Commerce

Public Works and Development Facilities Program (EDA)

U.S. Department of Housing and Urban Development

Community Development Block Grant Program (CPD)

U.S. Environmental Protection Agency

Brownfields Assessment Demonstration Pilots (OSWER)

Brownfields Cleanup Revolving Loan Fund Pilots (OSWER)

Brownfields Job Training and Development Demonstration Pilots (OSWER)

Sustainable Development Challenge Grants (OA)

Education and Research

Corporation for National Service

Learn and Serve America Program

U.S. Department of Agriculture

Sustainable Agriculture Research and Education (CSREES)

Water Quality Special Research Grants Program (CSREES)

U.S. Environmental Protection Agency

Environmental Education Grants Program (OEE)

Science to Achieve Results (ORD)

Environmental Justice

U.S. Environmental Protection Agency

Environmental Justice Grants to Small Community Groups (OEJ)

Environmental Justice Through Pollution Prevention Grants
Program (OEJ)

Forestry

U.S. Department of Agriculture

Cooperative Forestry Assistance Programs (FS)

Forestry Incentive Program (NRCS)

Indian Tribes

U.S. Department of Health and Human Services

Improving the Capability of Indian Tribal Governments to
Regulate Environmental Quality (ANA)

U.S. Department of Housing and Urban Development

Indian Community Development Block Grant Program (PIH)

U.S. Department of the Interior

Environmental Management on Indian Lands (BIA)

Forestry on Indian Lands (BIA)

Water Resources on Indian Lands (BIA)

U.S. Environmental Protection Agency

Clean Water Act Indian Set-Aside Grant Program (OWM)

Drinking Water SRF Tribal Set-Aside Program (OGWDW)

Indian Environmental General Assistance Program

Tribal Drinking Water Capacity Building /Indian

Grants (OGWDW)

Tribal Grants for Groundwater Protection Pesticide Management
Planning (OPPTS)

Mining

U.S. Department of the Interior
Abandoned Mine Land Reclamation Program (OSM)

Monitoring

U.S. Environmental Protection Agency
Environmental Monitoring for Public Access and Community Tracking (OEI)

Pollution Prevention and Control

Small Business Administration
Pollution Control Loans

U.S. Department of the Interior
Clean Vessel Act Grant Program (FWS)

U.S. Environmental Protection Agency
Chemical Emergency Preparedness and Prevention Technical Assistance Grants (CEPPO)
Pesticide Environmental Stewardship Grants (OppTS)
Pollution Prevention Incentives for States (OPPTS)

Watershed and Drinking Water Source Protection

U.S. Department of Agriculture
Watershed Protection and Flood Prevention Program (NRCS)

U.S. Department of Transportation
Transportation Equity Act for the 21st Century Funding Programs (FHWA)

U.S. Department of the Interior
Land and Water Conservation Fund Grants to States (NPS)

U.S. Environmental Protection Agency
Capitalization Grants for Clean Water State Revolving Fund (OWM)
Capitalization Grants for Drinking Water State Revolving Fund (OGWDW)
Great Lakes Program (GLNPO)
Nonpoint Source Implementation Grants (319 Program) (OWOW)
Water Quality Cooperative Agreements (OWM)
Watershed Assistance Grants (OWOW)

Wetlands

U.S. Department of Agriculture
Wetlands Reserve Program (NRCS)

U.S. Department of the Interior
Coastal Wetlands Conservation Grant Program (FWS)
North American Wetlands Conservation Act Grants Program (FWS)
National Coastal Wetlands Conservation Grant Program (FWS)
North American Wetlands Conservation Act Grants Program (FWS)

U.S. Environmental Protection Agency
Five Star Restoration Program (OWOW)
Wetlands Program Development Grants (OWOW)

Wildlife

National Fish and Wildlife Foundation.
Bring Back the Natives Grant Program

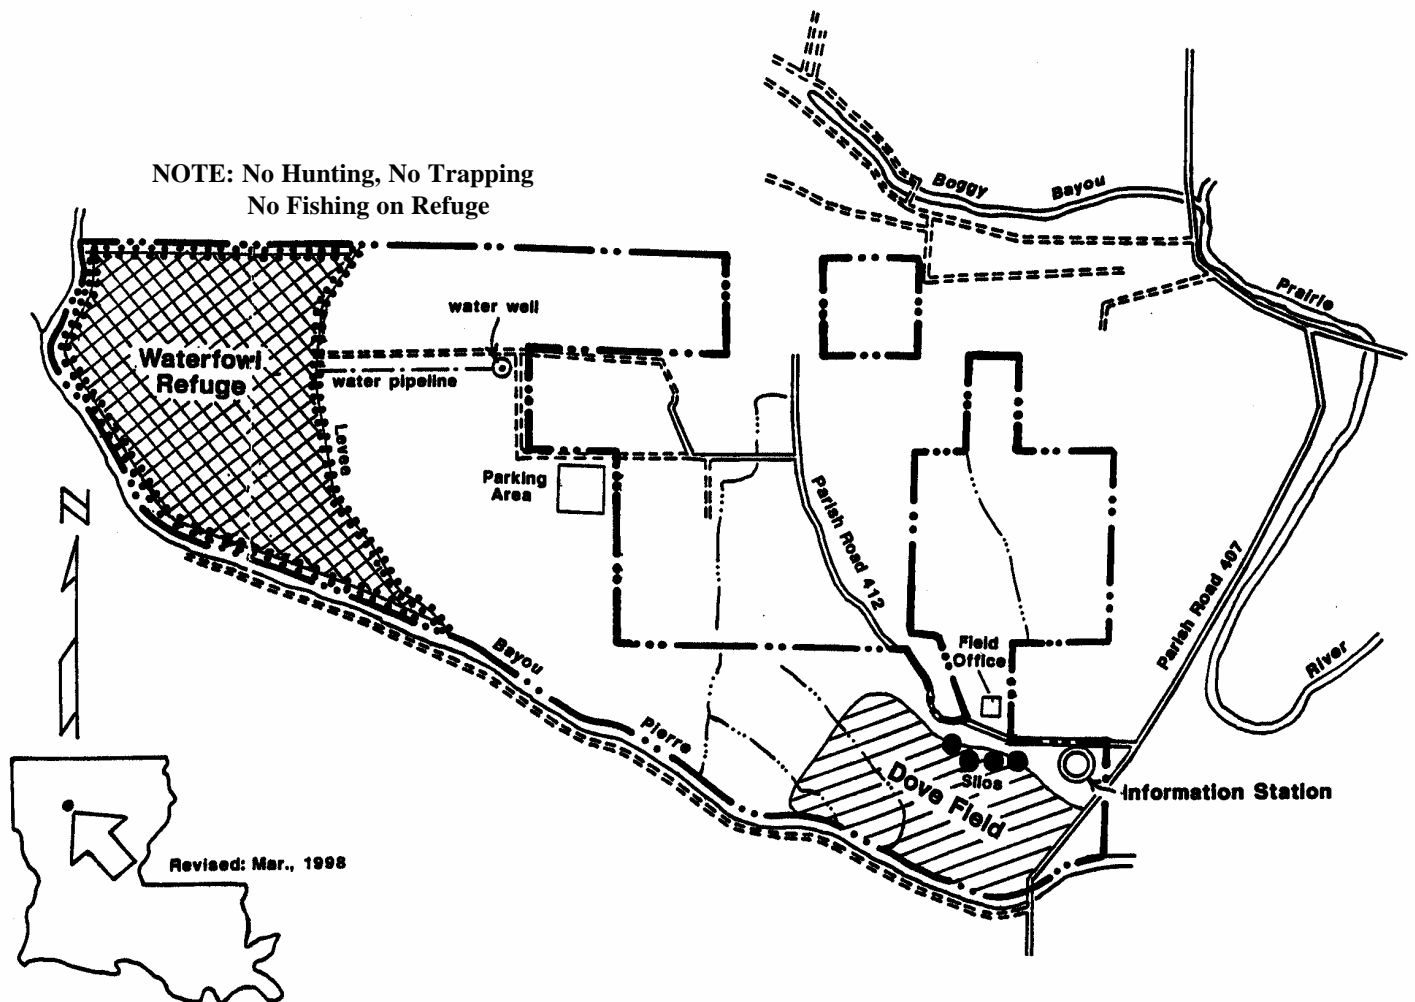

U.S. Department of Agriculture
Wildlife Habitat Incentives Program (NRCS)

U.S. Department of Commerce
Community-Based Restoration Program (NOAA)
Fisheries Development and Utilization Research and Development Grants and Cooperative Agreements Program (NOAA)

U.S. Department of the Interior
Partners for Fish and Wildlife Program (FWS)
Wildlife Conservation and Appreciation Program (FWS)

APPENDIX D. Resource Maps.

BAYOU PIERRE W.M.A.
OWNER: Louisiana Department of Wildlife and Fisheries
1,337 Acres

Directions to Bayou Pierre W.M.A.

From Shreveport

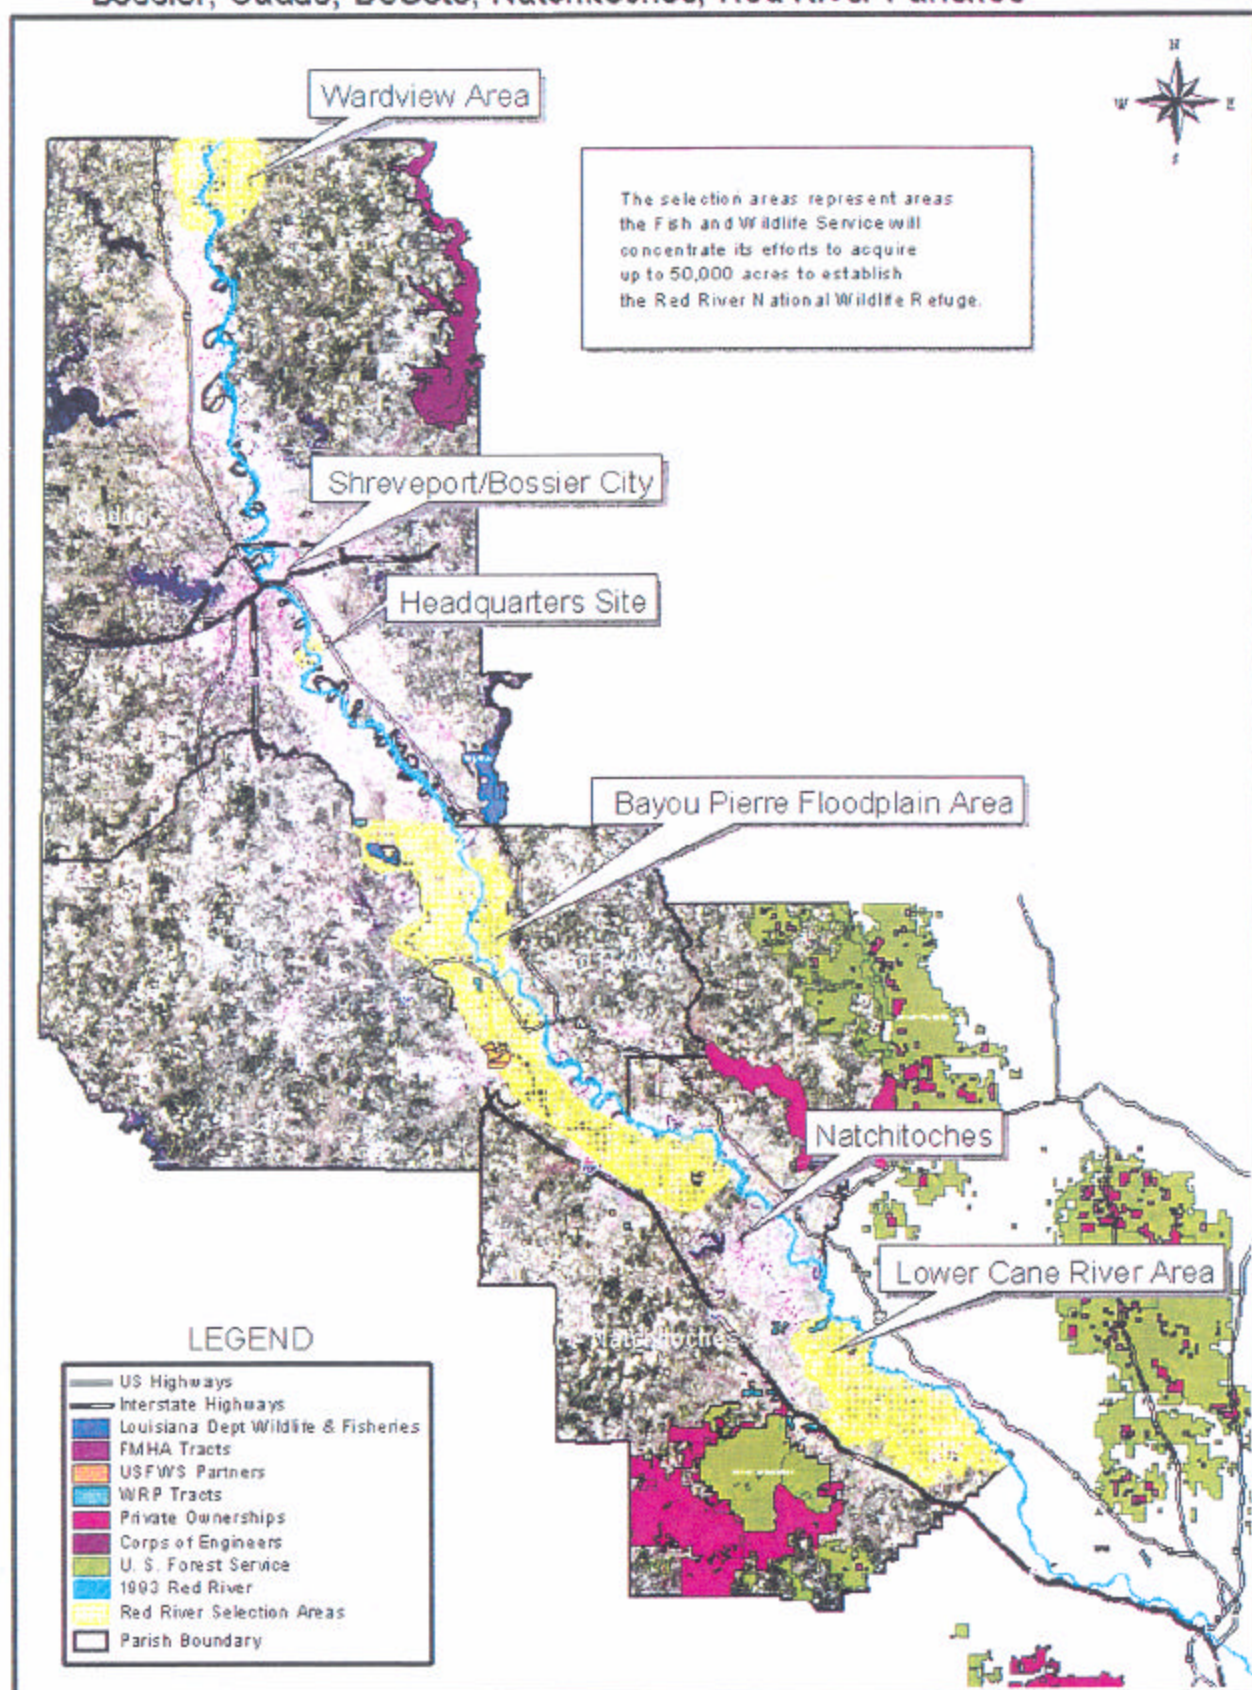

LA Hwy 1 South from Shreveport 15.2 miles south of LSUS; turn right onto Yearwood Road; go 4.5 miles and turn right onto Red River Road 407; go 1.1 miles to area.

From Armistead

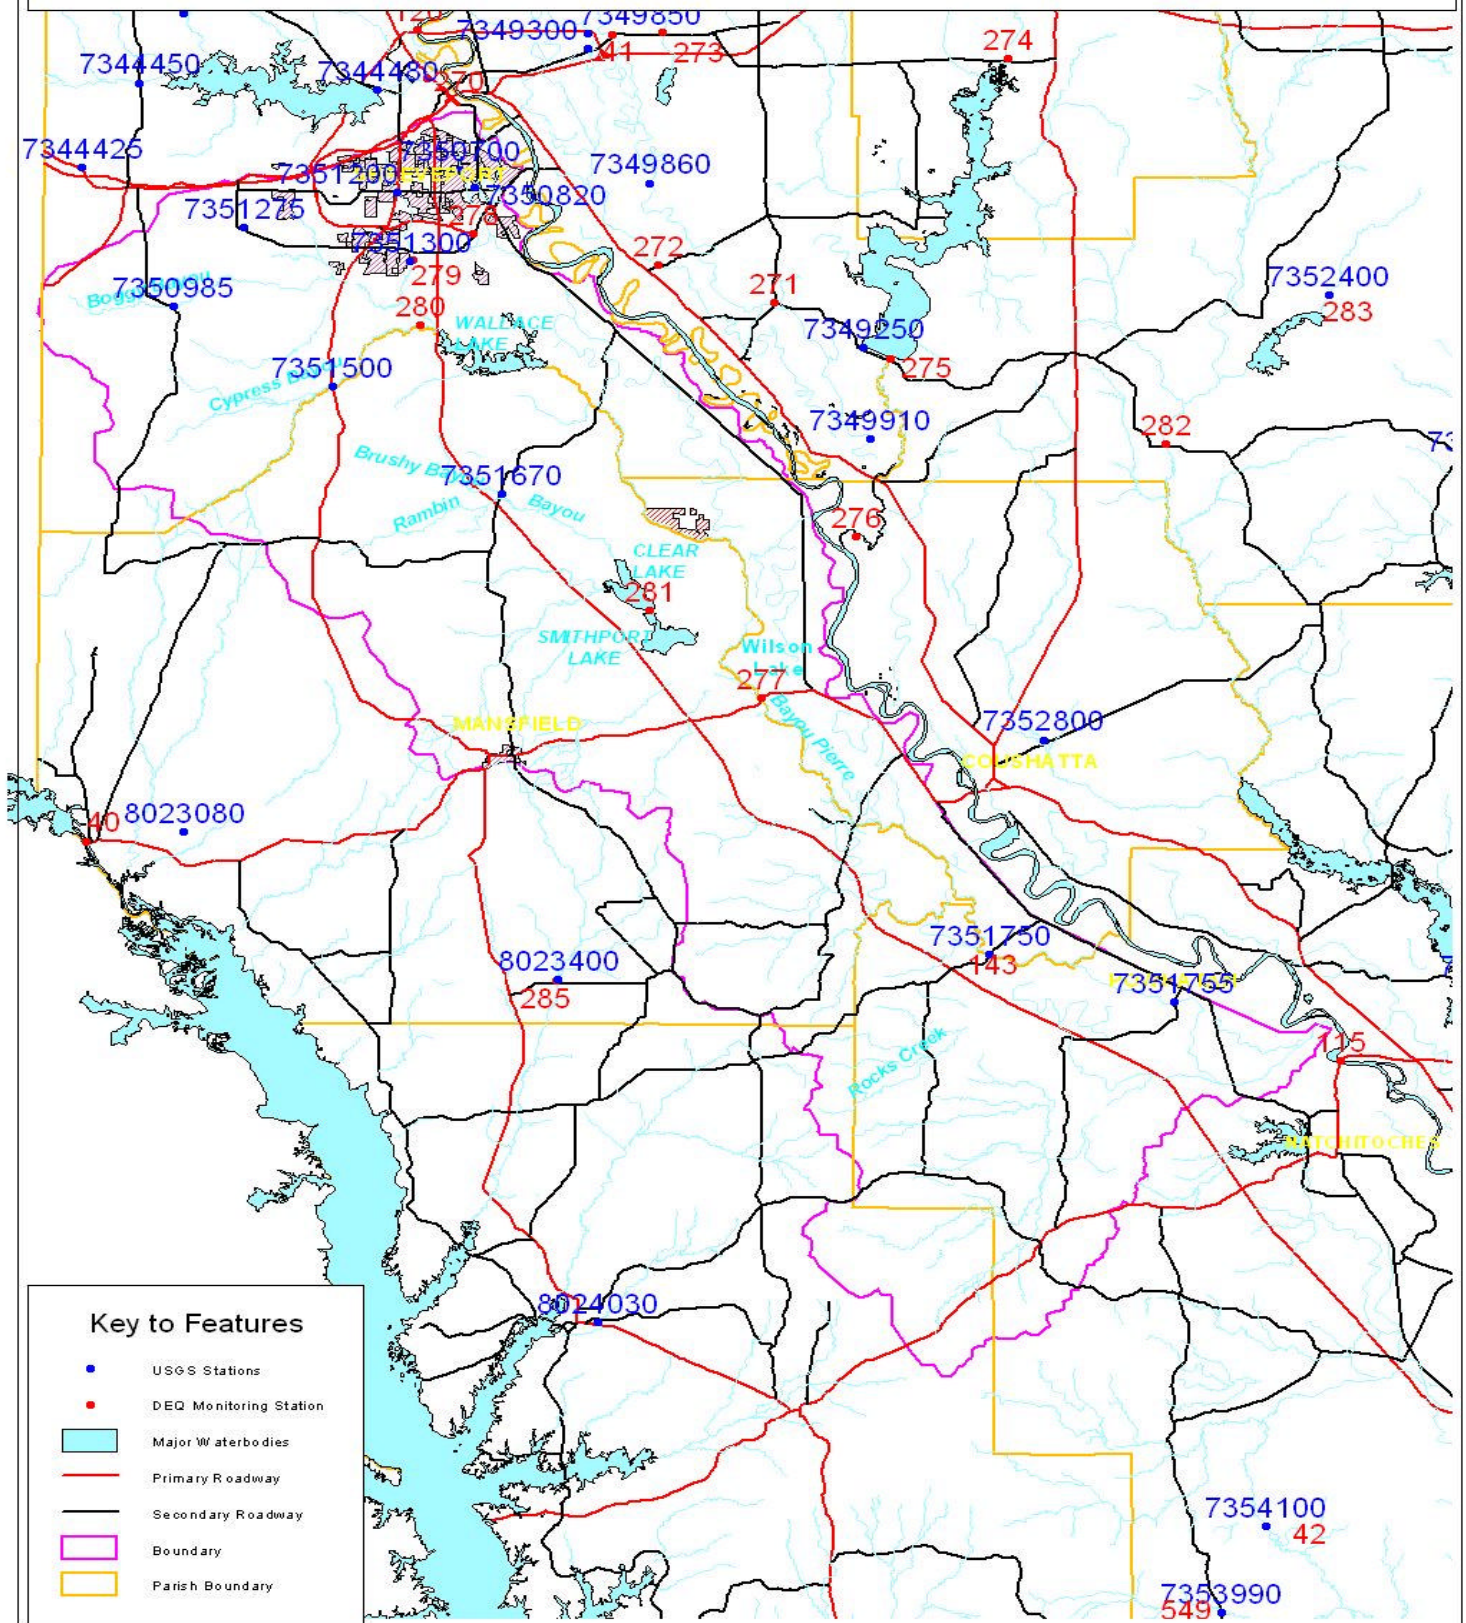

LA Hwy 1 North from Armistead 15.0 miles; turn left onto Red River Road 410; go 4.3 miles and turn left on Red River Parish Road 407; go 1.1 miles to area.

RED RIVER NATIONAL WILDLIFE REFUGE

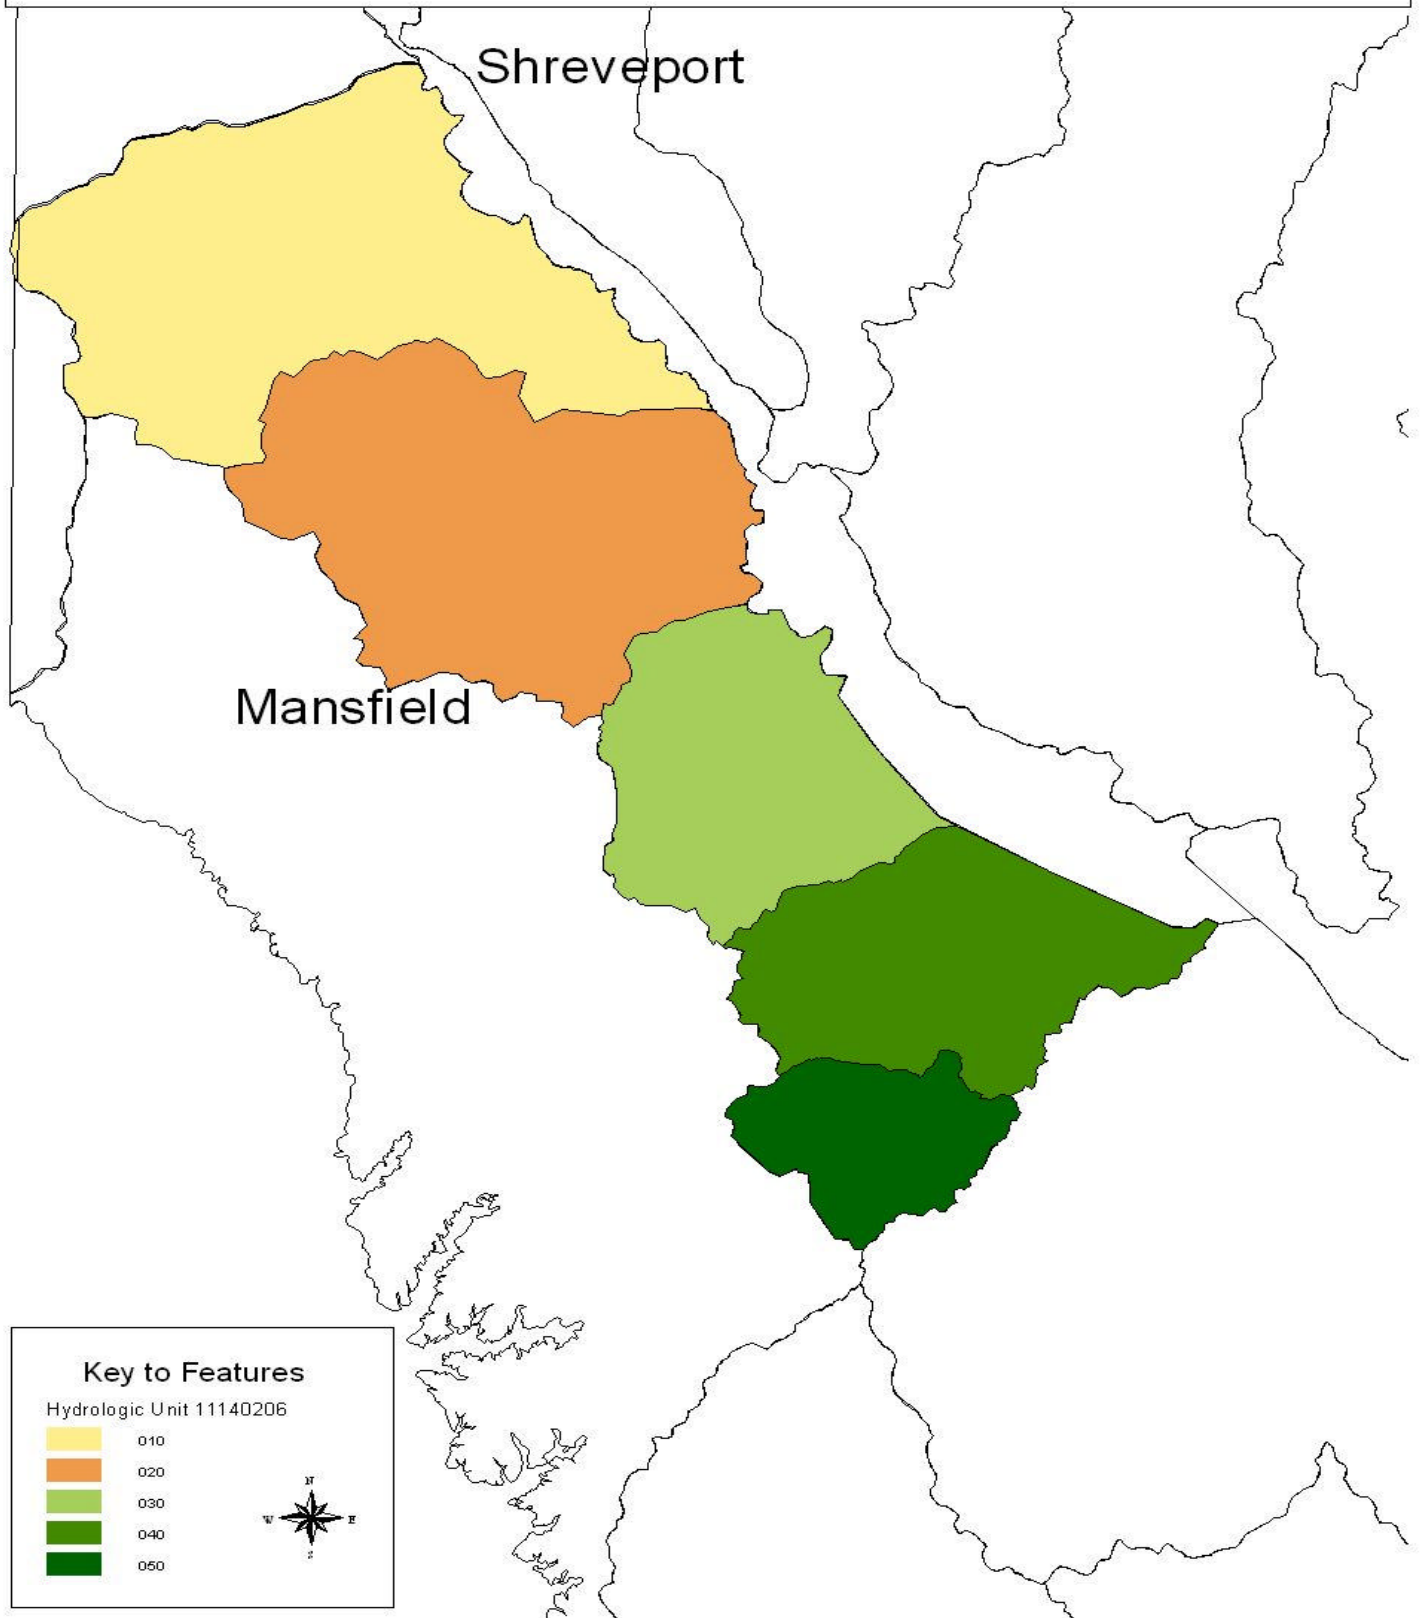

Bossier, Caddo, DeSoto, Natchitoches, Red River Parishes

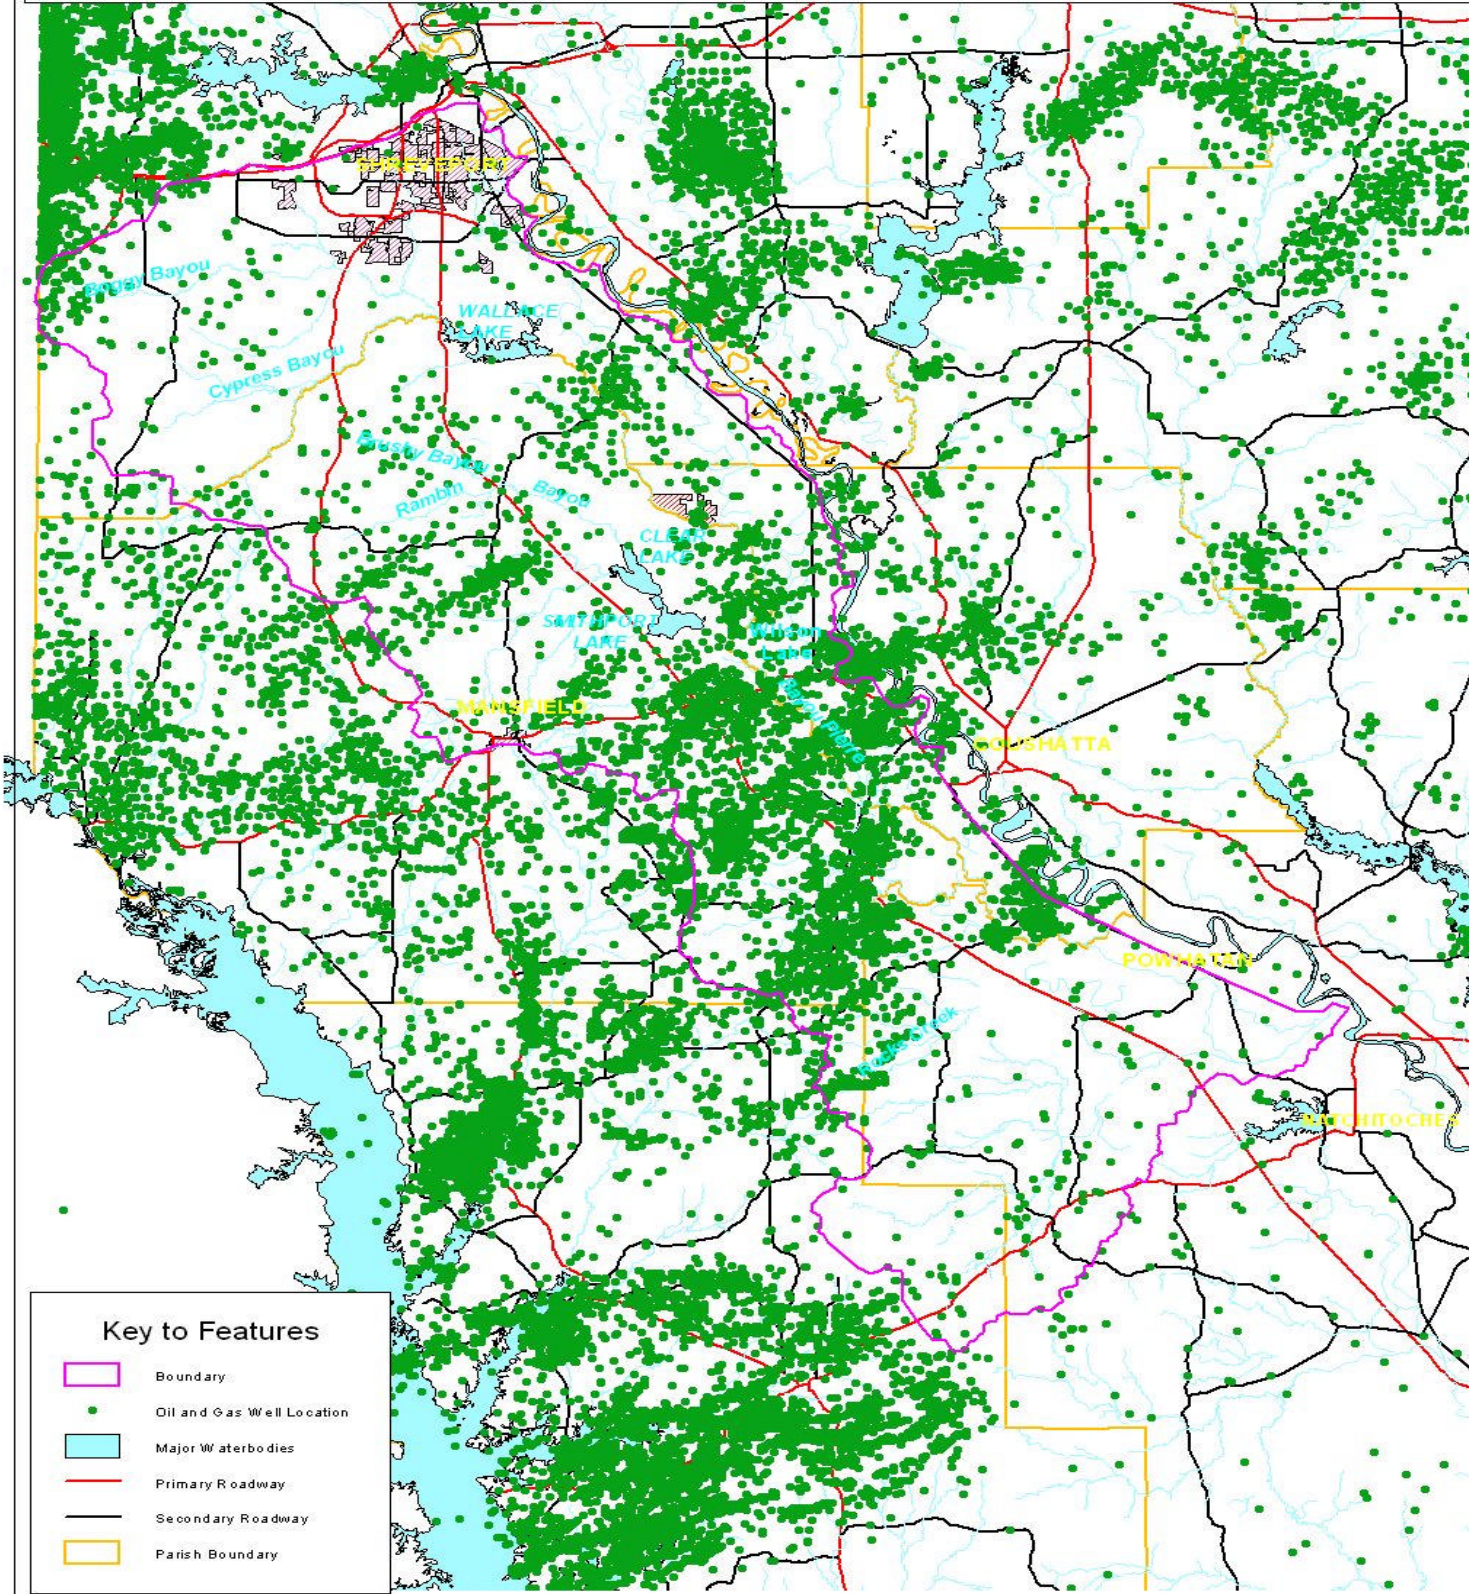

Bayou Pierre River Basin Study Monitoring Station Locations

Watershed Units within Bayou Pierre River Basin Study Area

Bayou Pierre River Basin Study Oil and Gas Well Locations

APPENDIX E. Prior Studies, Reports, and Existing Water Projects .

- Corps Report on Definite Project for Construction of a Dam at Wallace Lake, De Soto and Caddo Parishes, Louisiana, dated 21 December 1936.
- Corps Report on Definite Project for the Construction of a Dam at Wallace Lake, De Soto and Caddo Parishes, Louisiana (Revised), dated 15 June 1937.
- Corps Bases of Design for a Dam at Wallace Lake, De Soto and Caddo Parishes, Louisiana, dated 12 June 1939 and subsequent endorsements thereto.
- Corps Wallace Lake Dam, Cypress Bayou, Caddo and De Soto Parishes, Louisiana, Hydrology of the Basin as Related to Spillway Requirements, dated 21 June 1940 and revised 15 March 1941.
- Boggy Bayou – A Drainage Basin Study by B.C.M. Consultants for the Caddo Parish Police Jury, dated November 1979.
- Wallace Lake, Appendix II, Master Reservoir Regulation Manual, dated May 1975.
